Benjamin (Prof. A. C.), The Logical Structure of Science (*Review*), 904
Benjamin (M.), C. W. Cosgrove and G. W. Warren, Modern Receiving Valves: Design and Manufacture, 34
Benson (S. B.), Beavers in Michigan, 635
Benthsáth (A.), S. Rusznyák and Prof. A. Szent-Gyorgyi, Vitamin P, 326
Berg (Dr. L. S.), elected an honorary foreign member of the American Society of Ichthyologists and Herpetologists, 1014
Bergsøe (P.), A New Alloy of High Density, 886
Bernal (J. D.), and others, Air Raid Precautions, 760 and Dr. I. Fankuchen, Structure Types of Protein 'Crystals' from Virus-infected Plants, 923
Bernkopf (H.), [I. J. Kligler and], Inactivation of Vaccinia Virus by Ascorbic Acid and Glutathione, 965
Berthier (Mlle. Paulette), [C. Achard, A. Boutaric and], Viscosity of Solutions of Bile, 854
Bertl (E.), [Prof. R. Furth, F. Obořil and Dr. K. Sitte] Induced Radioactivity with Neutrons from Slow Deuterons, 716, Induced Radioactivity of Silver with Neutrons from Slow Deuterons, 964
Bertrand (G.), and L. Silberstein, Sulphur, Phosphorus and Nitrogen in Plants cultivated on a given Soil, 166; New Determinations of the amount of Boron in Plants cultivated on the same Soil, 813
Bessemens (Prof. A.), elected a member of the German Academy of Natural Sciences, Halle, 667
Bessey (Prof. E. A.), A Text-Book of Mycology (*Review*), 91
Best (R. J.), Visible Mesomorphic Fibres of Tobacco Mosaic Virus in Juice from Diseased Plants, 628
Beurlen (Prof. K.), elected a member of the Imperial Leopold Caroline German Academy, Halle, 442
Beveridge (Sir William), elected master of University College Oxford, 619, 643; work of, 619; Place of the Social Sciences in Human Knowledge, 1117: and others, Whither Population ?, 162
Bezssonoff (Prof. N.), and Mme. M. Woloszyn, Duality of the Reversibly Oxidized forms of Vitamin C and the Polarization of its Dienol Group, 469
Bhabha (Dr. H. J.), Negative Protons in Cosmic Radiations, 415; Experimental Test of the Proton-Neutron Exchange Interaction, 1021; 1103; and W. Heitler, Passage of Fast Electrons and the Theory of Cosmic Showers, 299
Bhagavantam (S.), and Dr. A. V. Rao, Raman Spectrum of Benzene Vapour, 114
Bhar (J. N.), Effect of Meteoric Shower on the Ionization of the Upper Atmosphere, 470
Bhatia (Lt.-Col. S. L.), Indian Physiology, 640
Bhatnagar (S. S.), P. L. Kapur and A. N. Kapur, Effect of a Magnetic Field on Adsorption, 515
Biggart (Dr. J. H.), appointed Musgrave professor of pathology in Queen's University, Belfast, 770
Bilger (G.), [R. Wavre and], Some Polygons of similar Attraction, 1031
Binger (Dr. L. G.), [death], 18
Binns (V.), and S. Bairstow, Locomotive Furnace Control, 119
Birch (T. T. C.), *Pinus radiata* in New Zealand, 475
Birkhoff (Prof. G. D.), elected president of the American Association for 1937; A Conceptual Theory of Atomic Structure, 203
Bishop (Dr. Ann), [Dr. H. P. Bayon and], Cultivation of *Histomonas meleagridis* from the Liver Lesions of a Hen, 370
Bishop (A. H. B.), and G. H. Locket, An Elementary Chemistry (*Review*), 394
on Bissing (F. W. Freiherr), Prof. A. Wiedemann, 1045
jerge (Dr. T.), Radioactive Neon, 757
lackburn (Dr. K. B.), and Dr. B. N. Temperley, Fossil Algæ in Boghead Deposits, 340
Blackett (Prof. P. M. S.), awarded the Hopkins prize of the Cambridge Philosophical Society, 686
Blacklock (Dr. J. W. S.), appointed St. Mungo (Notman) professor of pathology at the Glasgow Royal Infirmary, 208
Blackman (Dr. F. F.), presented with the Linnean gold medal of the Linnean Society of London; work of, 915
Bland-Sutton, Bt. (Sir John), [obituary article], 223
Bloch (Prof. J.), elected an honorary member of the Royal Asiatic Society, 442
Bloch (Mlle. Marie), [J. Dufay, J. Ellsworth and], Emission of CO+ Bands in the Head of Peltier's Comet (1936, *a*), 644
Blondel (Prof. A.), awarded the Faraday medal of the Institution of Electrical Engineers, 189
Blumenthal (M.), [M. Centnerszwer and], Thermal Dissociation of Lithium Nitrate, 167
Bobranski (Dr. B.), [Prof. E. Sucharda and], translated by Dr. G. W. Ferguson, Semimicro-Methods for the Elementary Analysis of Organic Compounds (*Review*), 392
de Boer (S.), and A. Brouwer, Action of Medicines on Auricular Fibrillation (2), 602
Bolliger (A.), Chemistry of Joffe's Reaction for Creatinine, 523
Bolsover (G. R.), [T. Swinden and], Controlled Grain Size in Steel, 254
Bomskov (Dr. C.), Methodik der Hormonsforschung. Band I (*Review*), 570
Bond (Dr. G.), Excretion from Leguminous Root Nodules, 675
von Bonde (Dr. C.), Cape Crawfish, 292
Booth (E.), Some Tests of Thermal Constants of Glass Bricks, 977
Booth (E. H.), Zonal Discordance in Diurnal Magnetic Variations, 523
Bor (J.), A Photo-electric Method for the Measurement of the Optical Constants of Metals, 716
Born (Prof. Max), Wave Mechanics of Couples (Neutron–Neutrino), 68
Borthwick (Prof. A. W.), [death], 705; [obituary article], 914
Bose (Prof. J. K.), Origin of Cross-Cousin Marriage in Assam, 328
Bose (P. K.), and B. B. Sarkar, Hæmostatic Action of Ayapin and Ayapanin, 515
Bossuet (R.), [P. Jolibois and], Quantitative Analysis of Metallic Solutions by means of the Spectrograph, 939
Bothe (W.), and W. Gentner, Artificial Radioactivity produced by means of γ-Rays, 555; Atomic Transmutations by means of γ-Rays, 722
Böttger (Dr. O.), Diamantine Compounds, 555
Bouin (Dr. P.), and Dr. Ancel, awarded the Albert I of Monaco prize of the French Academy of Medicine, 835
Bouligand (Prof. G.), elected *correspondant* of the section of mechanics of the Paris Academy of Sciences, 322
Bourdreau (Dr. F. G.), appointed executive director of the League of Nation's Milbank Memorial Fund, 408
Boutaric (A.), [C. Achard, Mlle. Paulette Berthier and], Viscosity of Solutions of Bile, 854; [C. Achard, Mme. Madeleine Roy and], Optical Activity of Sera and their Proteins separated by the Acetone Method in the cold, 1080
Bowden (Dr. F. P.), appointed Humphrey Owen Jones lecturer in physical chemistry in Cambridge University, 643; and T. P. Hughes, Surface Temperature of Rubbing Solids and the formation of the Beilby Layer, 152; Physical Properties of Surfaces (4), 1123
Bowen (E. G.), [R. A. Watson Watt, A. F. Wilkins and], Return of Radio Waves from the Middle Atmosphere, 277, 299
Bowen (E. J.), appointed a demonstrator in chemistry in Oxford University, 896
Boyd (A. W.), and Dr. A. L. Thomson, Return of Swallows to their Nesting Sites, 419
Braak (Dr. C.), Evaporation Records in the Netherlands, 970
Bragg (Sir William), Development of Crystal Analysis by X-Rays (Sir Henry Trueman Wood lecture), 104; Recent work in Crystallography, 228; Recent Crystallography, 865; 911

RP R269

Bragg (Prof. W. L.), Structure of Binary Alloys, 255; appointed director of the National Physical Laboratory; work of, 830; resignation from Manchester University, 854

Brammall (Dr. A.), and J. G. C. Leech, Hydrolysis of Rock-forming Minerals, 754

Brangwyn (Mrs.), awarded a Prix international du Tourisme, 103

Braunholtz (Dr. W. T. K.), appointed secretary of the Institution of Gas Engineers, 835

Brauns (Prof. R.), Mineralogie. Siebente Auflage (*Review*), 133

Brdička (Dr. R.), Dependence of the Polarographic Reaction of Proteins on Hydrogen Ion Concentration, 301; Application of the Polarographic Effect of Proteins in Cancer Diagnosis, 330; Polarographic Investigations in Serological Cancer Diagnosis, 1020

TITLE INDEX

α-Particles from the Radioactive Disintegration of a Light Element, Dr. W. B. Lewis, W. E. Burcham and W. Y. Chang, 24
Aberdeen University: Prof L. Hogben appointed regius professor of natural history, 65; Prof. J. S. Young appointed regius professor of pathology, 166; conferment of honorary doctorate on O. Bloch, N. Dunn, Prof A. W. Gibb and Dr. J. F. Tocher, 643; Gifts to, 975
Absorption: from the Intestine (*Review*), 309, Spectra, Optical Activity and Isotopic Exchange, C. H. Johnson and N. H. Poynton, 842
Accidents and their Prevention, Dr. H. M. Vernon (*Review*), 446
Acclimatize to High Altitudes, Ability to, Individual variations in, A. Keys, B. H. C. Matthews, W. H. Forbes, R. A McFarland and D. B. Dill, 812
Acetone, Photo-Decomposition of, R. Spence and W. Wild, 764
Actinometer, A Simple, A. Angstrom, 118
Adrenal: Cortical Hormone, Cholesterol and the, Dr. O. Rosenheim and Dr. H. King, 1015; Degeneration in a Pure Strain of Mice subject to Mammary Cancer, Dr. W. Cramer and E S Horning, 196; Cortex, Relation of the, to Cyclical Changes in the Female Accessory Reproductive Organs, Prof. C. N. H. Long and Dr. S. Zuckerman, 1106
Adsorption, Effect of a Magnetic Field on. S. S. Bhatnagar, P. L. Kapur and A. N. Kapur, 515
Aerial Attack, The Protection of the Public from, Cambridge Scientists' Anti-War Group (*Review*), 606
Aerodynamics, a Differential Equation met with in a Problem of, G. Tiercy, 977
Aeroplane Structures, Dr. A. J. S. Pippard and Capt. J. L. Pritchard. Second edition (*Review*), 780
Aeroplanes Lost at Sea, Search for, G. Claude, 1080
Afforestation in the Lake District, 144
Africa: Nationalism in, Lord Hailey, 169; Nationalism in, Native Races and, 169; Answers Back, H. H. Prince Akiki K. Nyabongo (*Review*), 214; Stone Age, an Outline of Prehistory in Africa, Dr. L S B. Leakey (*Review*), 454, West Tropical, Flora of, Dr J. Hutchinson and Dr. J. M Dalziel, Vol. 2, part 2 (*Review*), 985; Blood Groups in, 994
Agar-agar, Structure of, Dr. E. G. V. Percival, Dr. J. Munro and J. C. Somerville, 512
Agave, Cytology of, L. R. Doughty, 334
Age-Hardening, Theory of, Dr. M. L. V. Gaylor, 890
Agouti Coat, A New Factor for the, Dissociated in the Segregation of an Interspecific Crossing of Guinea Pigs, A. Pictet and M. A. Ferrero, 855
Agricultural: and Waste Lands of Wales, A Survey of the, edited by Prof. R. G. Stapledon (*Review*), 88; Surveys (*Review*), 88, Meteorology: Some Characteristics of Precipitation in Saskatchewan and Alberta, J. W. Hopkins, 145, Research Council, Report, October 1933–September 1935, 262; Botany, National Institute of, Seventeenth Report of the, 833; Chemistry, A Practical Course in, F. Knowles and Dr. J. E. Watkin (*Review*), 863; Abstracts, 960
Agriculture: British: Regional Types of, by Fifteen Authors, edited by J. P. Maxton (*Review*), 488; Survey of (*Review*), 488; Science and Practice of, Rao Bahadur B. Viswa Nath, 640; Chemistry and, 974; Rothamsted and, Annual Inspection of Plots; Message from Prof. H. E. Armstrong, 1027; as a Potential Source of Raw Materials in Industry, Sir Harold Hartley (Mather Lecture), 1046
Air: Raid Precautions Handbook, No. 4, 64, Resistance of Passenger Trains, F. C. Johansen, 206; in a Potash Mine in Catalonia, Electrical Conductivity of the, C. Dauzère, 208; Ministry, Department of the Air Member for Research and Development, Dr. D. R. Pye appointed director of scientific research and W. S. Farren deputy director of scientific research, 281; Raid Precautions and Air Disarmament, 364; Attack, The Civil Population and, 387; Conditioning in Modern Buildings, E. R. Dolby, 476; Raid Precautions, Major-Gen. C. H. Foulkes (*Review*), 606; Survey Committee, Report of the, No. 2, 622; Viscosity of, G. Kellstrom, 679; Raid Precautions, Dr. J. D. Bernal and others, 760; Major-Gen. C. H. Foulkes, 761; Mass Analysis, E. W. Hewson, 889; Ionization of, by Electrified Dielectrics, E. Perrier, 938; Flow of, with Velocities Higher than Sound through Holes of Very Small Diameter, L. Agostini, 1081; Velocity Meter, Portable, Filter Attachment to, 1116
Airy at Greenwich Observatory [1837], 39
Airy's Observations at Cambridge Observatory [1837], 425
Alchemical Manuscript, An, W. J. Wilson, 22
Alcohol: Apo-dehydrogenase from Yeast, Preparation of a Highly Active, M. Sreenivasaya, 112; and Motor Accidents, Dr. H. M. Vernon, 188
Aldehyde Mutase, Dr. M. Dixon and Dr. C. Lutwak-Mann, 548; Dr. D. Michlin, 926; Dr. M. Dixon and Dr. C. Lutwak-Mann, 927
Algebra, Higher, S. Barnard and J. M Child (*Review*), 569
Algeria, Evolution of the Rains in, since the French Colonization, P. Queney, 82
Algæ, New Species of, W. A. Setchell and N. L. Gardner, 721; from the Belfast Pan, Transvaal, F. E. Fritsch and F. Rich, 977
Aliphatic Aldehydes, Dipole Moments of some, Prof. J. R. Partington and Dr. I. Coomber, 510
Allantoicase, A New Enzyme, A. Brunel, 427
Alloy: A New, of High Density, Dr. C. J. Smithells, 490; P. Bergsøe, 886
Alloys Corrosion of, A Method of studying the, H. Triché, 771; Ferrous and Light, Researches on, Prof. G. Chaudron, 892; New, of the Elinvar Type Susceptible of Structural Hardening, P. Chevenard, L. Huguenin, X. Waché and A. Villachon, 1030
Alumina, 'Activated', Reactions caused by, Dr. R. S. Cahn and Dr. R. F. Phipers, 717
Aluminium-Legierungen, A. Grutzner. Unter mitarbeit von G. Apel. Teil 1; Teil 2, Prof. A von Zeerleder (*Review*), 268
American: Flood Devastation, 185; Association for the Advancement of Science: Atlantic City Meeting, Prof. H. B. Ward, 202; award of the association prize to Dr. W. M. Stanley; Prof. G. D. Birkhoff elected president for 1937, 203; Congress of Therapeutics, award of the gold key of merit and honorary membership of the, to Prof. S. Jellinek, 408
Amines, Action of Nitrous Acid on, J. C. Earl and N. G. Hills, 344
Amino Acid Solutions, Raman Effect as a Method of Analysis of, N. Wright and W. C. Lee, 551
Ammonia: Formation in Shed Blood and a Characteristic Deaminase of the Blood Stream, Prof. E. J. Conway and R. Cooke, 627; Volatilized from Soils, Estimation of, Prof. V. Subrahmanyan, 884
Ammoniacal Copper Sulphates, Thermal Decomposition of, E. Rencker and P. Vallet, 1081

Ammonium Chloride, Heavy, Transformation of, J. Weigle and H. Saini, 977
Amœba proteus (Y), Effect of Centrifuging on, B. N. Singh, 675
Amphibia, Germinal Layers and the Larva in, O. Mangold, 159
Amphibian Organization Centre, Nature of the, N. G. Heatley, C. H. Waddington and Dr. J. Needham (6), 342
Amphipod, An, *Eucrangonyx gracilis* S. I. Smith, new to Britain, G. I. Crawford, 327
Amtsarzt: Der, ein Nachschlagewerk fur Medizinal- und Verwaltungsbeamte, Dr. A. Gutt and others. Erste Folge (*Review*), 862
Analysis, Quantitative Inorganic, Textbook of, Prof. I. M. Kolthoff and Dr. E. B. Sandell (*Review*), 821
Anatolia, Prehistory of, Miss Winifred Lamb, 360
Anatomy, Journal of, "Elliot Smith Volume", 65
Anatomy: Practical, A Manual of, a Guide to the Dissection of the Human Body, Prof. T. Walmsley. New edition. In 3 parts. Part 1 (*Review*), 654
Anemographs, Sites for, M. J. Thomas, 554
Aneurin (= Vitamin B_1) in Urine, Determination of, by the Thiochrome Method, Dr. J. Goudsmit and Dr. H. G. K. Westenbrink, 1108
Animal: Painting: and Anatomy, W. F. Calderon *Review*), 6; Foundations of, Prof. A. Macphail (*Review*), 6; Behaviour, Institute for the Study of, 21; Sociality, F. F. Darling, 259; Magnetism, An Investigation into [1837], 383; Nutrition, Relation of, to Public Health in India, Col. A. Olver, 640; Deprived of a Labyrinth, Comparative Study of the Attitude of an, and the Attitude of a Normal Animal Standing on a Slope, R. Sulzer, 1031
Animals: Value of Experiments on, 146; Influence of Temperature Fluctuations on, J. S. Mikulski, 806
Animal's World, The, Prof. Doris L. Mackinnon (*Review*), 456
Anions in the Animal Kingdom, Active Absorption of, Prof. A. Krogh, 755
Anisfield, John, award given to Dr. J. S. Huxley and Dr. A. C. Haddon, 190
Annelids, Polychætous, of Japan, Prof. Okada, 1023
Annual Register, The, 1936, Edited by Dr. M. Epstein (*Review*), 947
Antarctica: New Coastline of, 321; First Crossing of, L. Ellsworth, 636
Anthraquinone Crystals, Atomic Parameters in, Determination of the, Prof. Bhagawati Charan Guha, 969
Anthropology, Cinematographic, A. M. Hocart (*Review*), 447
Antimalarials, Chemistry of, Prof. J. N. Ray, 638
Antiquities from Essex at the British Museum, 916
Apia Observatory, Research at, 543
Apples, Internal Cork of, H. O. Askew and E. Chittenden 34
Aquarist and Pond-keeper, March–April, 959
Aquariums and Fishponds, A. L. Wells (*Review*), 456
Archæological: Investigations in Western Asia, 360; Discoveries in Northern Syria, Sir Leonard Woolley, 1047
Architectural: Lighting, R. O. Sutherland, 145; Graphic Standards: for Architects, Engineers, Decorators, Builders and Draftsmen, C. G. Ramsey and H. R. Sleeper. Second edition (*Review*), 349
Arctic: Expedition, The Oxford University, 1935–36, A. R. Glen, 10; Marine Invertebrates, Biology of, G. Thorson, 635; Birds in New Zealand, R. A. Falla, 721; Development in the, H. P. Smolka, 917
Argentine Society for the Progress of Science travelling fellowships, awards of, 1063
Aristotelianism, Modern, Dr. H. Dingle, 784; Prof. H. Levy, 1025
Arithmetical Recreations, Dr. A. C. Aitken, 164
Armagh Observatory, Dr. E. M. Lindsay appointed astronomer at, 791
Aromatic Diazo-Compounds: in Industry (*Review*), 487; The, and their Technical Applications, K. H. Saunders (*Review*), 487
Arrow-straightener, Ivory, from Alaska, A. Digby, 74
Arsenic, Atomic Weight of, Křepelka and Kočnar, 76
Arsenites, Arsenates, Selenites and Selenates, Estimation of, Prof. J. Milbauer and Dr. J. Vodražka, 848
Arthropods, Primitive, 377
Arundo Donax L., Alkaloids from, Dr. J. Madinaveitia, 27
Arun River, The, and Himalayan Uplift, Dr. L. R. Wager, 679
Ascaris megalocephala, Effect of Ultra-centrifuging on the Egg of, Dr. R. L. King and Prof. H. W. Beams, 369
Ascorbic Acid: Combined in Plant Tissues, Prof. B. C. Guha and J. C. Pal, 843; and Hæmochromogens, Coupled Oxidation of, Dr. R. Lemberg, B. Cortis-Jones and M. Norrie, 1016
Ash Elements in the Cultivation of excised Root Tips, Importance of, W. J. Robbins, Virginia B. White, J. E. McClary and Mary Bartly, 209
Ashmolean Society [1837], 258
Asparagus Fly, A. S. Buckhurst, 291
Asiatic, Central, Gold Mines of the Bronze Age, 956
Associated Grocery Manufacturers Association of America, presentation of the annual award of the, to Dr. G. R. Minot, 148
Asteroid Nervous System, J. E. Smith, 888
Astronomical Society of the Pacific, award of the Catherine Wolfe Bruce gold medal to Prof. E. Hartzsprung and appointment to the Alexander F. Morrison memorial research associateship, 441
Astronomy: Teaching of, J. A. Edgar and others, 164; Indian, Scope and Development of, Sukumar Ranjan Das, 555
Athenæum Club: Dr. E. J Butler, Dr. J. B. Conant and Lord Hailey elected members of the, 148; Sir Warren Fisher, Prof. R. H. Fowler and Dr. W. B. Yeats elected members of the, 322
Athenæum, Science News in the [1837], 258
Athens: British School at, The Annual of the, No. 34. Session 1933–1934 (*Review*), 176; University, Centenary of, 749; University, Conferment of an Honorary Doctorate on Prof. F. G. Donnan, 1050
Atlantischen Ozeans, Schichtung und Zirkulation des, Prof. A. Defant. Lief. 3: Die Troposphare (*Review*), 1085
Atmosphere: Composition of the, T. M. Carpenter, 637; Upper Part of the, Ionization of the, Mme. Irène Mihul and C. Mihul, 938; Large Ions of the, Nature and Origin of the, G. Nadjakoff, 1030
Atmospheric: Electric Conductivity and the Current from Air to Earth, J. J. and P. J. Nolan, 259; Disturbances due to Thundercloud Discharges, Dr. F. W. Chapman, 711; Atmospheric Pollution, Conference on, 957
Atmospherics: Nature of, Prof. E. V. Appleton and Dr. F. W. Chapman, 334; at an Ionized Layer, Reflection of, Prof. T. H. Laby, F. G. Nicholls, A. F. B. Nickson and Dr. H. C. Webster, 837
Atom, The Spectroscope and the, Prof. A. Fowler (Thomas Hawksley lecture), 95
Atomic: Structure, A Conceptual Theory of, Prof. G. D. Birkhoff, 203; Transmutations, Further, by means of γ-Rays, W. Bothe and W. Gentner, 722; Nuclei: Intermediate nucleus in the Disintegrative Synthesis of, Disintegration in steps, W. D. Harkins, 729; Structure, a Theory of, C. F. Krafft, 996
Audubon: Miss Constance Rourke (*Review*), 776; The Magnificent (*Review*), 776
Aural Therapy in Relation to Deafness, late Prof. D. F. Fraser-Harris (*Review*), 94
Auricular Fibrillation, Action of Medicines on, S. de Boer and A. Brouwer (2), 602
Aurol Harmonics, Nature of, S. S. Stevens and C. A. G. Wiersma, 209
Aurora and the Zodiacal Light, Observations of the, 642
Auroras, Recent, and Magnetic Disturbances, Rev. J. P. Rowland, 375
Auroral Display: of February 3, 277; and Radio Disturbance, W. N. Craig, 318

Auroras: Red and Sunlit, Altitudes and Spectra of, Prof. C. Stormer, 584; Recent. The Solar and Magnetic conditions associated with, Rev. J. P. Rowland, 680; Solar Activity and, Eigenson and Gnevishev, 709; Magnetic Disturbances and, 790, Rev. J. P. Rowland, 835

Australia: appointment of a Wool Board in, 831; Commonwealth of, Official Year Book of the, No. 29, 1936, Dr. R. Wilson (*Review*), 985

Australian: Aquatic Phycomycetes, Kathleen M. Crooks, 125; Plants, Cyanogenetic Glucosides in, H. Finnemore and D. K. Large (6), 603

Austrian insignia for science and art, award of the, to Prof. H. Molisch, Dr. J. Wagner-Jauregg, Dr H. H. Meyer, Prof. O. Loisi and Prof. V. Hess, 322

Axial Flow Fans and Pumps. Data for the Design of, 1116

Ayapin and Ayapanin, Hæmostatic Action of, P. K. Bose and B. B. Sarkar, 515

Azimuths, Longitudes and, Astronomical Determination of, Prof. N. E. Norlund (George Darwin lecture), 894

Azotobacter of the Soil, Sensibility of the, to the Molecular Structure of the Monoxybenzoic Acids, G. Guittonneau and R. Chevalier, 125

β Hume-Rothery Phases, The Existence-Range of the, M. Hara, 195

β-Radioactivity, A Note on the Theory of, Dr. A. Mercier, 797

β-Ray: Transformation, Relations in, and the Neutrino Theory, Dr. H. O. W. Richardson, 505; Spectrum, the Continuous, Dr. F. L. Arnot, 1065

β-Rays, Visible Luminosity of Pure Fluids under the Influence of Hard, P. A. Čerenkov, 939

Back's Expedition, Capt. George, [1837], 1029

Bacilli, Spore-forming, Chromatin arrangements in, Dr. L. A. Allen, Miss J. C. Appleby and J. Wolf, 412

Bacteria in Sedimentary Phosphates of all Ages, Existence of numerous, L. Cayeux, 82

Bacteriology and Immunity, The Principles of, Prof. W. W. C. Topley and Prof. G. S Wilson. Second edition (*Review*), 456

Banks's, Sir Joseph, London House, 280

Bantry Bay District, Glaciation of the, A. Farrington, 118

Barents Sea, The Biological Station at, 725

Barlow, William Henry, on Lighthouse Illumination [1837] 769

Barra, Outer Hebrides, Natural History of, 338

Basalts, So-called Permanent Magnetization of, E. Thellier, 728

Bat, Brown, in Western North America, W. L. Engels, 419

Battersea Fields, Botany of [1837], 39

Bavarian Academy of Sciences: Prof. R. Hess elected an honorary member of the, 1014; Prof. O. Hahn elected a corresponding member of the, 1063

Beaver and other Indians of Canada, Anthropometry of, J. C. B. Grant, 932

Beavers in Michigan, S. B. Benson, 635

Bechuanaland, Witchcraft in, 749

Bed Bug, Destruction of the, S. A. Ashmore and A. W. McKenny Hughes, 706

Bees, Brood Diseases of, Investigation into, Dr. H. L. A. Tarr, 319

Beetles of Jehol, 764

Behavior: Primitive, an Introduction to the Social Sciences, W. I. Thomas; Dr. R. Money-Kyrle (*Review*), 778

Beilby Layer, Formation of the, Surface Temperature of Rubbing Solids and the, Dr. F. P. Bowden and T. P. Hughes, 152

Beilby, Sir George, Memorial Fund, awards from the, to Dr. B. S. Evans and Dr. W. H. J. Vernon, 189

Belfast, Queen's University, Dr. J. H. Biggart appointed Musgrave professor of pathology, 770

Bellevue Electromagnet, Particles of High Energy in the Cosmic Radiation in the Magnetic Field of the, L. Leprince-Ringuet and J. Crussard, 300

Bengal, A Compendium of (*Review*), 485

Bengal Chemist, Life and Experiences of a, Sir Prafulla Chandra Rây. Vol. 2 (*Review*), 485

Benthic Amphipoda of the North-Western North Sea and Adjacent Waters, D. S. Raitt, 976

Benzene: Vapour, Raman Spectrum of, S. Bhagavantam and Dr. A. V. Rao, 114; Long Wave Spectroscopy of, 555; Structure of, s-Trideuterobenzene and the, C. R. Bailey, A. P. Best, R. R Gordon, J. B. Hale, Prof. C. K. Ingold, A. H Leckie, L. H. P. Weldon and C L. Wilson, 880

Berberis vulgaris, Production of Uredia and Telia of *Puccinia graminis* on, Dr. Margaret Newton and Dr. T. Johnson, 800

Berenice, East India Company's S.S. [1837], 340

Berlin Society of Ethnology, Anthropology and Primeval History, award of the Rudolf Virchow medal to Prof. H. F. K. Gunther, 408

Bermuda Oceanographical Station, The, Prof. E. W. MacBride, 948

Bern University Psychiatric Clinic, gift to, by the Rockefeller Foundation, 281

Beryllium: Chemical detection of Helium formed in, by Gamma Rays, Prof. F. A. Paneth and Dr. E. Gluckauf, 712; Absorption of γ-Rays Measured by their Photo-effect in, J. Rotblat, 963; Bromide in some Synthetical Reactions, R. Pajeau, 1081

Beta Ray Disintegration, The, Prof. C. D. Ellis and others; Dr. A. N. May, 477

Bi-bivalent Salts in very dilute Aqueous Solution, Degree of Dissociation of, E. A. O'Connor, 151

Biblical Archæology, Appeal for a chair in, 579

Bile: Pigment Hæmochromogens in Nature, Occurrence of, and their formation from Hæmatin and Hæmoglobin, R. Lemberg and R. A. Wyndham, 522; Solutions of, Viscosity of, C. Achard, A. Boutaric and Mlle. P. Berthier, 854

Binary: Mixtures, Viscosity of, Dr. E. L. Lederer, 27; Alloys, Structure of, Prof. W. L. Bragg, 255

Biochemistry, Comparative, An Introduction to, Dr. E. Baldwin (*Review*), 819

Bio-Climatology (*Review*), 90

Biogeography, A New Method in, Dr. B. P. Uvarov, 493

Biological: Time, Dr. Lecomte du Nouy (*Review*), 94; Stain for General Purposes, A new, Prof. H. G. Cannon, 549; Control, Research on, Dr. W. R. Thompson, 552; Station at Barents Sea, The, 725; Material, Ultimate Composition of, D. A. Webb and W. R. Fearon (1), 728

Biologie mathématique, Prof. V. A. Kostitzin (*Review*), 943

Biology: A Modern, E. J. Holmes and Dr. R. D. Gibbs (*Review*), 737; in the School, H. A. Peacock (*Review*), 864; Mathematical, Sir D'Arcy W. Thompson (*Review*), 943

Bird: -Song, The Study of (*Review*), 132; Migration, New Light on, Capt. B. Acworth, 362; Preservation, 440; Sanctuaries, British, 502; Ringing, British, Present State of, 833; -Migration, Study of, 957

Birds: Wild, Songs of, E. M. Nicholson and L. Koch (*Review*), 132; of the Greek Classics, D. Caclamanos (*Review*), 305; of Tropical West Africa: The, with special reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria, D. A. Bannerman. Vol. 4 (*Review*), 352; Secondary Sexual Characters in, Control of, Dr. E. Witschi, 377; of Paradise of the Arru Islands [1837], 479; of the South Orkney Islands, R. A. B. Ardley, 514; Muscles of the Pelvis Appendage in, G. E. Hudson, 806

Birmingham: Conference on Industrial Physics, Dr. H. R. Lang, 600; University: conferment of doctorates on D. Parkinson, R. A. Robinson and H. A. Thomas, 39; Dr. H. P. Newsholme appointed professor of hygiene and public health in, 479; New studies in, Sir Charles Grant Robertson, 499; bequests by Lady Scott-Moncrieff and Prof. R. F. C. Leith, other gifts; transference of the Mining Research Laboratory to the Imperial College of Science and Technology, 520; gift of A. E. Hills; Dr. R. Peierls appointed professor of applied mathematics, 726

Birth- and Death-Rates for 1936 in England, 189; Rate Problems, Statistics of, Prof. A. M. Carr-Saunders, 845
Bivalent Tin and Lead, Stereochemistry of, Dr. E. G. Cox, A. J. Shorter and Dr. W. Wardlaw, 71
Blood, Shed, Ammonia formation in, and a Characteristic Deaminase of the Blood Stream, Prof. E. J. Conway and R. Cooke, 627
Boll-worms of Cotton in South Gujerat, B. P. Deshpande and N. T. Nadkarny, 515
Boltonian, The Crayfordian and, Industries, J. Reid Moir and J. P. T. Burchell, 676
Boltzmann's H-Theorem, Prof. S. Chapman, 931
Bone, Morphogenetic Factors of (*Review*), 1036
Bones: a Study of the Development and Structure of the Vertebrate Skeleton, Dr. P. D. F. Murray (*Review*), 1036
Bonn University, Prof. K. Schmidt appointed rector of, 107
Bopyrids, Japanese, Dr. S. M. Shuno, 117
Boron: Hydrides of, Dr. E. Wiberg, 381; and the Control of Plant Disease, Dr. Winifred E. Brenchley, 536; in Plants Cultivated on the same Soil, New Determinations of the amount of, G. Bertrand and L. Silberstein, 813
Botanical Society of America, election of officers; Dr. N. I. Vavilov, Dr. Agnes Arber and Prof. L. R. Parodi elected corresponding members, 147
Boulder Dam: and its Equipment, 105, J. L. Savage, 706
Boulton, Matthew, H. W. Dickinson (*Review*), 443
BrSiC$_3$, Structure of, studied by means of Electron Diffraction, Prof. M. de Hemptinne and J. Wouters, 928
Brain in Marsupial Animals, Structure of the [1837], 165; Comparative Anatomy of the [1837], 685
Brass Strip, Rolled, Directional properties in, Dr. M. Cook, 847
Brassica Hybrids, Cytology of, Dr R. H. Richharia, 1024
Breeding: Tests and Variations, Dr. J. S Huxley, 331; Seasons, Light and, Dr. J. R. Baker, 414
Breeze and Clinker Aggregates, 339
Brewster: and Forbes [1837], 727; Sir David, on the Absorption of Light [1837], 812
Britain's Scenic Beauty (*Review*), 945
British: Broadcasting Corporation, The, 19; Museum (Natural History), resignation of G. C. Robson, 19; N. B Kinnear and Dr. H. A. Baylis appointed deputy keepers of zoology in the, 65; Medical Association [1837], 81, Empire Cancer Campaign, Grants from the, 106; Isles, Races in the, Dr. G. B. Morant, 143; Colonial Possessions, Demography of, Major P. G. Edge, 144; Films and the Cinema, 145; Geographers, Institute of, Annual Meeting, 163; Museum (Natural History), Recent acquisitions at the, 187; Empire Cancer Campaign · gift of a silver trophy by Lord Nuffield in furtherance of the, 190; acceptance by the Duke of Gloucester of the presidency of the, 243; Industries Fair, 317; Electrical and Allied Industries Research Association, Sixteenth Annual Report, 336; Industries Fair, 380; Museum (Natural History), Recent acquisitions at the, 405; Science Guild, review of the, 406; Chemical Industry and European Affairs, Dr. H. Levinstein, 437; Museum, Rt. Hon. W. G. A. Ormsby-Gore and Sir Henry Tizard elected trustees of the, 503; Engineers abroad and their Prospects, 563; Empire Cancer Campaign, grants of the, 666; Isles, Temperature and Sunshine in the, 679; Non-Ferrous Metals Research Association, Lt.-Col. J. H. M. Greenly elected chairman of the, 710; Association, The Nottingham meeting of the, 743; -American Understanding, J. Wickham Murray; H. G. Wells, 748; Museum (Natural History), Recent acquisitions at the, 750; Universities, A Yearbook of (*Review*), 779; Neuroptera, A Monograph of the, F. J. Killington. Vol. 1 (*Review*), 780; Scientific Instrument Research Association, resignation of directorship of research by Dr. H. Moore; appointment of A. J. Philpot, 795; Association, Arms for the, 831; Museum (Natural History), retirement of Dr. G. F H. Smith; Lt.-Col. W. Campbell Smith appointed keeper of minerals in the, 873; Research Organizations, American, Tour of, 918; Speleological Society, proposed institution of a museum, 919; Health Resorts: Spa, Seaside, Inland. Edited by Dr. R. F. Fox, 919; Pottery Manufacturers' Federation, Dr. M. Francis appointed director of research to the, 960; Social Hygiene Council, Prof. J. Young elected chairman of the Medical Advisory Board of the, 1014; Trees and Shrubs, including those commonly planted, Dr. H. Gilbert-Carter (*Review*), 1039; Honduras, Human Skeletal Material from, W. D. Hambly, 1114
Broadcasting: Receivers, Testing, Dr. R. L. Smith-Rose, 363; Modern Developments in, Sir Noel Ashbridge, 439, Ultra-Short Wave, 439; in 1936, 663; the Post Office and, Sir George Lee, 709; and the Coronation, 747
Bronze Age Cemetery near Glasgow, J. H. Maxwell and others, 20
Bronzes from Iran and elsewhere, Sidney Smith, 846
Brunel on the Thames Tunnel [1837], 643
Brussels: Museum, Iguanodons in the, 15; University, Opening of a School of Criminological Science, 107
Buchan, The case for (*Review*), 861
Buchan's Days: a Modern Guide to Weather Wisdom, E. L. Hawke (*Review*), 861
Buchner, Georg, Lorenz Oken und, J. Strohl (*Review*), 489
Buenos Aires, National Academy of Medicine, Prof. W. B. Cannon elected a corresponding member of the, 107
Builders' Estimates and Pricing Data. their Preparation and Analysis, H. A. Mackmin. Second edition (*Review*), 1089
Building: Exhibition, Science and, 421; Research, Progress in, 598
Buildings and Landscape, Conservation of, 345
Buist, John, and the Elementary bodies of Vaccinia, Dr. M. Gordon, 541
Bulbs, Hot-water Treatment of, 515
Bulinus and *Physopsis*, Some Characteristics of, F. G. Cawston, 977
Bulwer's Petrel in Britain [1837], 811
Burnes, Alexander, in Sind [1837], 383
Bushman: Hybrids, 20; Skull, Significance of the, Dr. T. F. Dreyer, 20, 37; Art, Records of, 621
Butterflies of the genus *Erebia* (*Review*), 265

^{12}C, Isotopic Weight of, Dr. F. W. Aston, 922
C-Neutrons, Temperature Equilibrium of, Dr. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 922
CO, '3*A*' Bands of, Rotational Analysis of the, Dr. R. Schmid and Dr. L. Gero, 928
Cactus Eaters, The, J. A. Weston (*Review*), 1039
Caddis Flies of India, Prof. A. B. Martynov, 33
Cadmium: at Low Temperatures, Magneto-resistance effect in, C. J. Milner, 384; Zinc and, Anomalous Expansion of, near the Melting Point, W. F. Hachkovsky and P. G. Strelkov, 715
Calcium Iodate as a Temporary Preservative, H. F. Steedman, 1072
Calculating Machines in Scientific Computing, 851
Calculus, Differential and Integral, Prof. R. Courant. Translated by Prof. J E. McShane. Vol. 2 (*Review*), 352
Calf of Man, presentation of the, to the National Trust by F. J. Dickens, 362
Californians, Hardy, Mrs. Lester Rowntree (*Review*), 1039
Cambridge: Philosophical Society, award of the Hopkins prize to Prof. P. M. S. Blackett, 686; University: award of the Clerk Maxwell scholarship to E. Bretscher, 39; D. V. Davies and Dr. W. R. M. Morton appointed demonstrators in anatomy; Prof J. A. Ryle elected a professorial fellow of Gonville and Caius College; W. E. Burcham elected Stokes student in physics at Pembroke College; Prof. H. A. Harris elected a professorial fellow of St. John's College, 166; Dr. G. P. McCullagh elected a fellow of Queen's College, 208; Prof. W. J. de Haas appointed Scott lecturer for 1937–38, 257; G. E. Briggs appointed reader in plant physiology; award

of the Raymond Horton-Smith prize to Dr. F. Goldby and Dr. J. Gray; T. Dalling elected professor of animal pathology and Dr. R. G. W. Norrish professor of physical chemistry, 341; L. C. G. Clarke appointed director of the Fitzwilliam Museum, 406; D. H. Barron appointed lecturer in anatomy; plans for a new school of Anatomy; award of the Sedgwick prize to Dr. E. C. Bullard and Dr. F. C. Phillips; Dr. J. Gray elected professor of zoology, 426; impending retirement of Sir Joseph Barcroft; appointment of Prof. E. D. Adrian as professor of physiology, 436; award of Smith's prizes to E. R. Love and H. R. Pitt and a Rayleigh prize to H. M. Cundy, 479; impending retirement of Prof. T. C. Hodson; Dr. J. H. Hutton appointed William Wyse professor of social anthropology, and G. Bateson, William Wyse student in social anthropology, 497; R. G. Hawtrey appointed Alfred Marshall lecturer for 1937–38; grants made from the Worts Fund; additional teaching officers recommended, 520; K. C. Dixon and D. G. Champernowne elected fellows of King's College, 560; retirement of Prof. A. Hutchinson, 577; Dr. F. P. Bowden appointed Humphrey Owen Jones lecturer in physical chemistry; S. D. Elliott appointed demonstrator in pathology; Dr. R. van de R. Woolley appointed John Couch Adams astronomer and first assistant observer at the observatory; J. W. S. Pringle awarded the Amy Mary Preston Read scholarship, 643; award of the Wyse studentship to G. Bateson, 686; award of the Adams prize to W. V. D. Hodge; Dr. A. C. Offord, F. Smithies and R. A. Lyttleton elected fellows of St John's College; Prof. R. G. W. Norrish elected a professorial fellow of Emmanuel College; Prof. Lennard-Jones proposed as director of a new mathematical laboratory, 854; award of the Gordon Wigan prize to A. E. Alexander and T. P. Hughes, 896; Dr. J. A. Todd appointed lecturer in mathematics, Dr. D. Stockdale and Dr. F. B. Kipping lecturers in chemistry and Dr. P. Tate lecturer in parasitology, 938; Dr. H. Hamshaw Thomas appointed reader in plant morphology, Dr. W. B. Lewis lecturer in physics, Dr. H. Carmichael and E. S. Shire demonstrators in physics and Dr. W. C. Price and Dr. E. A. Moelwyn-Hughes demonstrators in chemistry; G. L. Clark elected Sheepshanks exhibitioner; Dr. J. H. Schulman proposed second assistant director of research in colloid science, 975; Prof. H. R. Dean elected vice-chancellor, 1079

Canada: Education in, Dr. F. H. Spencer, 664; Indians of, Hon. T. A. Crerar, 1099

Canadian: Hydro-Electric Power Development in 1936, Dr. B. Cunningham, 558; National Research Council Scholarships, award of, 959

Cancer: Physico-Chemical Factors in, Dr. A. H. Roffo, 160; Mammary, Adrenal Degeneration in a Pure Strain of Mice subject to, Dr. W. Cramer and E. S. Horning, 196; Genetics of, Dr. L. Kreyberg, 253; second International Congress of the Scientific and Social Campaign against. Vol. 1, Reports, 255; Diagnosis, Proteins in, Application of the Polarographic Effect of, Dr. R. Brdička, 330; Diagnosis, Serological, Polarographic Investigations in, Dr. R. Brdička, 1020; and Diet: with Facts and Observations on Related Subjects, Dr. F. L. Hoffman (*Review*), 1086

Canning Practice and Control, O. Jones and T. W. Jones (*Review*), 946

Capacities, measurement of, Utilization of Relaxation Oscillations for the, R. Guillien, 644

Cape: Crawfish, Dr. C. von Bonde, 292; Verde Islands, Racial Crosses in, Prof. A. A. Mendes-Correa, 635

Carbon Monoxide, Ionization Potential of, J. Savard, Prof. M. de Hemptinne and P. Capron, 427

Carboniferous Limestone near Cork, Faunal succession in the, J. S. Turner, 426

Carbonyl Sulphide, J. Milbauer, 301

Carborundum, Origin of Uni-Polar Electrical Conductivity of, Dr. S. R. Khastgir, 28

Carboxyl Group, Absorption Spectrum of the, in the Vacuum Ultra-Violet, W. M. Evans and W. C. Price, 630

Cardium edule, Rate of growth of Totally Submerged, J. McCloy, J. M. Dodd, H. C. Davies, F. B. J. Edmonds and Prof. J. H. Orton, 799

Carnegie: Trust for the Scottish Universities, Report for 1935–36, 623; Corporation of New York, grants to Colonial officers for scientific research, 710

Carotene: Therapy of Retinitis Pigmentosa, Dr. E. M. Josephson and Dr. M. Freiberger, 155; from a Wood-Oil, Isolation of, Dr. V. M. Trikojus and Prof. J. C. Drummond, 1105

Carpel, Anatomy of the, Dr. Mabel S. Fraser, 1073

Casein, Researches on, E. Cherbuliez and J. Jeannerat, 1031

Catalysis, Associated Phenomena of, J. Milbauer, 301

Catalytic Reactions at High Pressures and Temperatures, V. N. Ipatieff (*Review*), 695

Catgut, Sterilized, for Surgical Use, 320

Cave Man in Texas, U.S.A., Mrs. R. G. L. Ayer, 253

Cell Death, Mechanism of, by High Pressures, B. Luyet, 939

Cells *in vitro*, growth of, Action of Radium Rays on the, Prof. L. Halberstadter and L. Doljanski, 841

Celtic and Saxon Art in Early England, 791

Cellulose: Wall, Structure of a, Dr. R. D. Preston and Dr. W. T. Astbury, 595; Crystalline Structure of, Prof. K. H. Meyer, 599

Centrifugal Pump, The Modern, as a Plankton Collector, S. G. Gibbons and J. H. Fraser, 417

Cephalopods and Crustaceans, Nerve Fibres in, J. Z. Young, 292

Ceramic, A New, 917

Cereal Rusts on Incompatible Hosts, Dr. Theodora B. Hanes, 34

Ceric Ions, Photochemical Reduction of, by Water, Dr. J. Weiss and Dr. D. Porret, 1019

Cerne Giant, The, 876; A Correction, 920

Chance: A World of, or, Whence, Whither and Why?, Prof. E. G. Spaulding (*Review*), 904

Chandhu-Daro, Sind, Excavations at, 537

Change of Life in Men and Women, Dr. Marie Carmichael Stopes (*Review*), 310

Chemical: Plant, Making of, 21; Plant Growth Substances, Two new, R. Snow, 27; Analysis, Magneto-Optic Method of, G. Hughes, 119; Reactions, Transition state in, Prof. M. Polanyi (Bedson lecture), 278; Carcinogenic Agents, Prof. J. W. Cook and others, 291; Engineers, Institution of, medal awards of the, 406; Calculations: Industrial, the application of Physico-Chemical Principles and Data to problems of Industry, Prof. O. A. Hougen and Dr. K. M. Watson. Second edition (*Review*), 457; Engineering, Elements of, Prof. W. L. Badger and Prof. W. L. McCabe. Second edition (*Review*), 457; Research Institute, Warsaw, 519; Kinetics, The Transition state in, Prof. M. Polanyi, 575; Engineering, Exhibition of, 663; Industry: Society of, award of the medal of the, to Prof. G. G. Henderson, 706; Index to Acts of Parliament and Statutory Rules and Orders affecting the, Second edition, 752; and Bacterial Analysis of Water and Sewage, Laboratory Manual for, Prof. F. R. Theroux, E. F. Eldridge and Prof. W. Le Roy Mallman. Second edition (*Review*), 822

Chemist in Industry, The, 682

Chemistry: Inorganic, Gmelin's (*Review*), 48; of Essential Oils, Prof. J. Read (Streatfeild memorial lecture), 80; School Certificate, A. Holderness and L. Lambert (*Review*), 217; Elementary, An, A. H. B. Bishop and G. H. Locket (*Review*), 394; Institute of, Dr. R. H. Pickard, 404; Infancy of, Dr. E. J. Holmyard (*Review*), 452; Prelude to, An Outline of Alchemy, its Literature and Relationships, Prof. J. Reed (*Review*), 452; General, Recent Advances in, Dr. S. Glasstone (*Review*), 458; Inorganic, A Text-Book of, Edited by Dr. J. Newton Friend. Vol. 6, Part 5: Antimony and Bismuth, W. E. Thorneycroft (*Review*), 458; Physical: Recent Advances in, Dr. S. Glasstone. Third edition (*Review*), 458; Prof. F. H. MacDougall (*Review*), 458; Inorganic, A Survey of Modern Developments, Sir Gilbert T. Morgan and F. H. Burstall (*Review*), 566; Recent Progress in, Dr. A. E. H. Tutton (*Review*), 566; Organic: Essential Principles of, Prof. C. S. Gibson (*Review*), 652; in Theory and Practice (*Review*), 652; Practical, Dr. F. G. Mann and Dr. B. C. Saunders (*Review*), 652; the Chemistry of the Compounds of Carbon, Prof. L. J. Desha (*Review*), 652; Lecture Experiments in, G. Fowles (*Review*), 780; Analytical (*Review*), 821, Agricultural, A Practical Course in, F. Knowles and Dr. J. E. Watkin (*Review*), 863, and Agriculture, 974

Cherty Limestone with *Planorbis hardmani* Wade from the Mt. Elder Range, Kimberley District, W.A., F. Chapman, 1031

Chicago University, gift by the Rockefeller Foundation, 408

Chick Embryo, Glucolysis without Phosphorylation in the, Dr. J. Needham and H. Lehmann, 368

Children, Young, in European Countries, 542

Chile, Medical Society of, award of the Corbalan Melgarejo prize to J. L. Valenzuela, 667

Chili, Medicine in, [1837], 340

China: Early Man in, Sir Grafton Elliot Smith, and work on, W. C. Pei, 192; Botany in, Prof. H. H Hu, 319

Chinese Medical Journal, Supplement to the, 22, Art, Modern, Prehistoric Motives in, C Schuster, 158; Culture Before and After Indianization, Prof. Hu Shih, 233

Chlorella vulgaris, Effect of Auxin on, H. C. Yin, 897

Cholesterol and the Adrenal Cortical Hormone, Dr. O. Rosenheim and Dr. H. King, 1015

Christian Church and War, 276

Christ's Hospital and Prof. Armstrong, 876

Chromatographic Analysis, Inorganic, Schwab and Jockers, 335

Chromium, Electrolytic, Hardness of, M. Cymboliste, 854

Churning for Butter, Dr. W. Clayton and J. F. Morse, 717

Cilicia, Archæological Investigations in, Prof. J. Garstang, 876

Cinematography, Colour, Major A. B. Klein (*Review*), 307

Cinque Ports Barons returned to Parliament, 1366 to 1722, Alderman T. S. Dymond, 1121

Cirripedia of the Arabian Sea, H. G. Stubbings, 635

Citizenship and the Universities, 106

Citrus Culture in Egypt, T. W. Brown, revised by Abbas el Sawy, 970

Civil: Population, The, and Air Attack, 387; Engineers, Institution of, Completion of Building, 957; [1837], 1121

Clarke's Electrical Measuring Instruments, [1837], 383

Clay, Baked, Magnetization of, E. Thellier, 342

Climatic Discomfort, W. F. Tyler, 79

Climatology, A Modern (*Review*), 820

Clinical Science: The Field of, Lord Nuffield's Gifts to Oxford, Prof. T. R. Elliott, 177

Clock, Post Office Speaking, in Great Britain, Dr. E. A. Speight and O. W. Gill, 892

Clocks and Time Keeping, Studies in (6), Prof. R. A. Sampson, 40

Clouds, Natural and Artificial, Prof. D. Brunt (Symons memorial lecture), 541

Coal: Oxidation of, B. Juettner, R. C. Smith and H. C. Howard, 637; Scottish Jurassic, Fossil Pollen in, Dr. J. B Simpson. 673; Gas Industry, Future of the, 995

Cobaltammines, Complex, Interchange of Hydrogen Isotopes in, F. W. James, Dr. J. S. Anderson, and Prof. H. V. A. Briscoe, 109

Cobaltic Chloride, Mlle. Denise Hibert and C. Duval, 686

Cobaltous Compounds, Variable Magnetic Moments of, E. D. P. Barkworth and Prof. S. Sugden, 374

Cochlea: Human, Electrical Stimulation of the, C. S. Hallpike and Prof. H. Hartridge, 192; Electrical Stimulation of the, E. Bárány, 633; Effect, Origin of the, O. Gatty and Dr. A. F. Rawdon-Smith, 670

Coefficients, Activity, from Cells with Transference, T. Shedlovsky and D. A. MacInnes, 848

Cœlenterates, Japanese, Dr. T. Komai, 158

Cœlomic Fluids of Invertebrates, Corpuscles in, T. Ohuye, 33

Colchicin, Effects of, and of *Viscum album* Preparations upon Germination of Seeds and Growth of Seedlings, L. Havas, 371

Colloids and the Biological Effect of Radiation, R. T. M. Haines, 32

Colonial Office Appointments, 107; 281; 667; 877, 1063

Colorado Potato Beetle, Order Concerning the, 64

Color Changes of Animals in Relation to Nervous Activity, Prof. G. H. Parker (*Review*), 457

Colour: -Blindness and Hæmoglobin in Man, Linkage between the Genes for, Julia Bell and Prof. J. B. S. Haldane, 426; Code for Biology, A (*Review*), 530

Columbia University, award of the Charles Frederick Chandler medal to Dr. J. H. Northrop, 148

Combustible Liquids, A Machine for Classifying, According to their Advance in Inflammation under the Conditions of Use in Compression Ignition Motors, P. Clerget, 644

Combustion Levels, Prof. W. T. David, 67

Comet: 1936*a*, Observations of, P. Rossier, 209; A New, 441; Whipple (1937*b*), 582

Comets, 365; 503; 835

Commensalism between a Marine Mussel, an Anemone, and Several other Organisms, D. L. Fox and R. T. Young, 882

Commonwealth Fund Fellowships, appointments to, 920

Compositæ, Quantitative Evolution in, J. Small and I. K. Johnston, 40

Computing, Scientific, Calculating Machines in, 851

Comte: the Founder of Sociology, F. S. Marvin (*Review*), 268

Concrete: Construction, Principles of Plain and Reinforced, Dr. E. Probst (*Review*), 349; Reinforced (*Review*), 349

Condamine's Pyramid at Quito, Restoration of, [1837], 937

Condensation Coefficients of Various Substances, Prof. T. Alty, 374

Condensers, Time Discharge of, W. A. Yager, 75

Conics, Elementary, Analytical, Dr. J. H. S. Bailey (*Review*), 461

Constants for Band Spectra, Calculation of, Dr. C. H. Douglas Clark, 508

Contact Catalysis, The Mechanism of, Dr. R. H. Griffith (*Review*), 1088

Continental Masses, Oceanic Basins and, Permanence of, Sir Thomas Holland (Huxley memorial lecture), 809

Coorgs, An Ethnographical Study of the, Dr. Dewan Bahadur L. K. Ananthakrishna Iyer, 639

Copenhagen, Museums of, [1837], 1121

Copepods, Parasitic, from Belgium, J. H. Schuurmans Stakhoven, jun., 763

Copper, Radioactive Isotopes of, Dr. E. A. Oeser and J. L. Tuck, 1110

Coral Reef, Effect of Cyclone on, F. W. Moorhouse, 334

Cordierite in Pegmatites from Japan, H Shibata, 476

Cordyceps and *Isaria* Fungi, T. Petch, 159

Coronation: Broadcasting and the, 747; The Ceremonial of the, 773, Planting Schemes, 793; Honours, 829; Decorative Lighting for the, 832; Broadcast, 873; Ode, Dr. Marie Stopes's, 1013

CORRESPONDENCE

α-Particles from the Radioactive Disintegration of a Light Element, Dr. W. B. Lewis, W. E. Burcham, and W. Y. Chang, 24

Absorption Spectra, Optical Activity and Isotopic Exchange, C. H. Johnson and N. H. Poynton, 842

Adrenal: Degeneration in a Pure Strain of Mice Subject to Mammary Cancer, Dr. W. Cramer and S. E. Horning, 196; Cortical Hormone, Cholesterol and the, Dr. O. Rosenheim and Dr. H. King, 1015; Cortex, Relation of the, to Cyclical Changes in the Female Accessory Reproductive Organs, Prof. C. N. H. Long and Dr. S. Zuckerman, 1106

Agar-agar, Structure of, Dr. E. G. V. Percival, Dr. J. Munro and J. C. Somerville, 512

Air Raid Precautions, J. D. Bernal and others, 760; Major-Gen. C. H. Foulkes, 761

Alcohol Apo-dehydrogenase from Yeast, Preparation of a Highly Active, M. Sreenivasaya, 112

Aldehyde Mutase: Dr. M. Dixon and Dr. C. Lutwak-Mann, 548; Dr. D. Michlin, 926; Dr. M. Dixon and Dr. C. Lutwak-Mann, 927

Aliphatic Aldehydes, Dipole Moments of Some, Prof. J. R. Partington and D. I. Coomber, 510

Alloy, A New, of High Density, P. Bergsøe, 886

Alumina, 'Activated', Reactions Caused by, Dr. R. S. Cahn and Dr. R. F. Phipers, 717

Amino Acid Solutions, Raman Effect as a Method of Analysis of, N. Wright and W. C. Lee, 551

Ammonia: Formation in Shed Blood of a Characteristic Deaminose of the Blood Stream, Prof. E. J. Conway and R. Cooke, 627; Volatilized from Soils, Estimation of, Prof. V. Subrahmanyan, 884

Amœba proteus (*Y*), Effect of Centrifuging on, B. N. Singh, 675

Amphipod, An, *Eucrangonyx gracilis*, S. I. Smith, New to Britain, G. I. Crawford, 327

Aneurin (= Vitamin B_1) Determination of, in Urine by the Thiochrome Method, Dr. J. Goudsmit and Dr. H. G. K. Westenbrink, 1108

Anions in the Animal Kingdom, Active Absorption of, Prof. A. Krogh, 755

Anthraquinone Crystals, Determination of the Atomic Parameters in, Prof. Bhagawati Charan Guha 969

Aristotelianism, Modern, Prof. H. Levy, 1025

Arundo Donax L., Alkaloids from, Dr. J. Madinaveitia, 27

Ascaris megalocephala, Effect of Ultra-Centrifuging on the Egg of, Dr. R. L. King and Prof. H. W. Beams, 369

Ascorbic Acid: Combined, in Plant Tissues, Prof. B. C. Guha and J. C. Pal, 843; and Hæmochromogens, Coupled Oxidation of, Dr. R. Lemberg, B. Cortis-Jones and M. Norrie, 1016

Atmospheric Disturbances Due to Thundercloud Discharges, Dr. F. W. Chapman, 711

Atmospherics at an Ionized Layer, Reflection of, Prof. T. H. Laby, F. G. Nicholls, A. F. B. Nickson and Dr. H. C. Webster, 837

Auroræ, Recent, and Magnetic Disturbances, Rev. J. P. Rowland, 375

Auroras, Red and Sunlit, Altitudes and Spectra of, Prof. C. Störmer, 584

β Hume-Rothery Phases, The Existence-Range of the, M. Hara, 195

β-Radioactivity, A Note on the Theory of, Dr. A. Mercier, 797

β-Ray: Transformations and the Neutrino-Theory, Relations in, Dr. H. O. W. Richardson, 505; Spectrum, The Continuous, Dr. F. L. Arnot, 1065

$BrSiCl_3$, Structure of, Studied by Means of Electron Diffraction, Prof. M. de Hemptinne and J. Wouters, 928

Bacilli, Spore-Forming, Chromatin Arrangements in, Dr. L. A. Allen, Miss J. C. Appleby and J. Wolf, 412

Beilby Layer, Formation of the, Surface Temperature of Rubbing Solids and the, Dr. F. P. Bowden and T. P. Hughes, 152

Benzene: Vapour, Raman Spectrum of, S. Bhagavantam and Dr. A. V. Rao, 114; Structure of, *S*-Trideuterobenzene and the, C. R. Bailey, A. P. Best, P. R. Gordon, J. B. Hale, Prof. C. K. Ingold, A. H. Leckie, L. H. P. Weldon and C. L. Wilson, 880

Berberis vulgaris, Production of Uredia and Telia of *Puccinia graminis* on, Dr. Margaret Newton and Dr. T. Johnson, 800

Beryllium, Chemical Detection of Helium Formed in, by Gamma Rays, Prof. F. A. Paneth and Dr. E. Gluckauf, 712; Absorption of γ-Rays Measured by their Photoeffect in, J. Rotblat, 963

Bi-bivalent Salts, in very dilute Aqueous Solution, Degree of Dissociation of, E. A. O'Connor, 151

Binary Mixtures, Viscosity of, Dr. E. L. Lederer, 27

Biological: Stain, A New, for General Purposes, Prof. H. Graham Cannon, 549; Control, Research on, Dr. W. R. Thompson, 552

Birth-Rate Problems, Statistics of, Prof. A. M. Carr-Saunders, 845

Bivalent Tin and Lead, Stereochemistry of, Dr. E. G. Cox, A. J. Shorter, and Dr. W. Wardlaw, 71

Blood, Shed, Ammonia Formation in, and a Characteristic Deaminase of the Blood Stream, Prof. E. J. Conway and R. Cooke, 627

Boltonian, The Crayfordian and, Industries, J. Reid Moir and J. P. T. Burchell, 676

Boltzmann's *H*-Theorem, Prof. S. Chapman, 931

Breeding: Tests and Variations, Dr. J. S. Huxley, 331; Seasons, Light and, Dr. J. R. Baker, 414

^{12}C, Isotopic Weight of, Dr. F. W. Aston, 922

C-Neutrons, Temperature Equilibrium of, Dr. O. R. Frisch, Dr. H. von Halban, jun. and Dr. J. Koch, 922

CO, '3*A*' Bands of, Rotational Analysis of the, Dr. R. Schmid and Dr. L. Gero, 928

Cadmium, Zinc and, Near the Melting Point, Anomalous Expansion of, W. F. Hachkovsky and P. G. Strelkov, 715

Calcium Iodate as a Temporary Preservative, H. F. Steedman, 1072

Cancer: Mammary, Adrenal Degeneration in a Pure Strain of Mice Subject to, Dr. W. Cramer and E. S. Horning, 196; Diagnosis, Application of the Polarographic Effect of Proteins in, Dr. R. Brdička, 330; Diagnosis, Serological, Polarographic Investigations in, Dr. R. Brdička. 1020

Carborundum, Origin of the Uni-Polar Electrical Conductivity of, Dr. S. R. Khastgir, 28

Carboxyl Group, Absorption Spectrum of the, in the Vacuum Ultra-Violet, W. M. Evans and W. C. Price, 630

Cardium edule, Totally Submerged, Rate of Growth of, J. McCloy, J. M. Dodd, H. C. Davies, F. B. J. Edmonds and Prof. J. H. Orton, 799

Carotene Therapy of Retinitis Pigmentosa, Dr. E. M. Josephson and Dr. M. Freiberger, 155; From a Wood-Oil, Isolation of, Dr. V. M. Trikojus and Prof. J. C. Drummond, 1105

Cells *in vitro*, Action of Radium Rays on the Growth of, Prof. L. Halberstadter and L. Doljanski, 841

Centrifugal Pump, The Modern, as a Plankton Collector, S. G. Gibbons and J. H. Fraser, 417

Ceric Ions, Photochemical Reduction of, by Water, Dr. J. Weiss and Dr. D. Porret, 1019

Chemical Plant Growth Substances, Two New, R. Snow, 27

Chick Embryo, Glucolysis without Phosphorylation in the, Dr. J. Needham and H. Lehmann, 368

China, Early Man in, Sir Grafton Elliot Smith and work on, W. C. Pei, 192

Cholesterol and the Adrenal Cortical Hormone, Dr. O. Rosenheim and Dr. H. King, 1015

Churning for Butter, Dr. W. Clayton and J. F. Morse, 717

Coal, Scottish Jurassic, Fossil Pollen in, Dr. J. B. Simpson 673

Cobaltammines, Complex, Interchange of Hydrogen Isotopes in, F. W. James, Dr. J. S. Anderson and Prof. H. V A. Briscoe, 109

Cobaltous Compounds, Variable Magnetic Moments of, E. D. P. Barkworth and Prof. S. Sugden, 374

Cochlea: Human, Electrical Stimulation of the, C. S. Hallpike and Prof. H. Hartridge, 192; Electrical Stimulation of the, E. Bárány, 633

Cochlear Effect, Origin of the, O. Gatty and Dr. A. F. Rawdon-Smith, 670

Colchicin, Effects of, and of *Viscum album* Preparations upon Germination of Seeds and Growth of Seedlings, L. Havas, 371

Colloids and the Biological Effect of Radiation, R. T. M. Haines, 32

Combustion Levels, Prof. W. T. David, 67

Commensalism between a Marine Mussel, an Anemone, and Several other Organisms, D. L. Fox and R. T. Young, 882

Condensation Coefficients of Various Substances, Prof. T. Alty, 374
Constants for Band Spectra, Calculation of, Dr C. H. Douglas Clark, 508
Copper, Radioactive Isotopes of, Dr. E. A. Oeser and J. L. Tuck, 1110
Corticosteron: A Crystallized Compound with the Biological Activity of the Adrenal-Cortical Hormone, P. de Fremery, E. Laqueur, Prof. T. Reichstein, R. W. Spanhoff, and I. E. Uyldert, 26; Activity of, in the Glucose Test in Rats, Prof. T. Reichstein, Prof. F. Verzár and L. Laszt, 331
Cosmic: Radiation, Longitude Effect of, and the Position of the Earth's Magnetic Centre, Dr. M. S. Vallarta, 24; Rays, Sidereal Time Periodicity of, and its Phase Shift, Dr. J. Barnóthy and Dr. M. Forró, 1064
Radiations, Negative Protons in, H. J. Bhabha, 415; Ray: Shower, Diurnal Variation of, Dr. M. Forró, 633; Showers, Y. Watase, 671; Rays and the Magnetic Moment of the Sun, Dr. M. S. Vallarta, 839
Cosmological Constants, The: Prof. P. A. M. Dirac, 323; Dr. S. Chandrasekhar, 757
Couples (Neutron-Neutrino), Wave Mechanics of, Prof. Max Born, 68
Crayfordian and Boltonian Industries, The, J. Reid Moir and J. P. T. Burchell, 676
Cross-Cousin Marriage in Assam, Origin of, Prof. J. K. Bose, 328
Crystallized Compound, Partial Synthesis of a, with the Biological Activity of the Adrenal-Cortical Hormone, Marguerite Steiger and Prof. T. Reichstein, 925
Crystals, Graphite, Abnormal Unidirectional Diamagnetism of, Temperature Variations of the, Prof. K. S. Krishnan and N. Ganguli, 155
Cucumber Viruses 3 and 4, Liquid Crystalline Preparations of, F. C. Bowden and N. W. Pirie, 546
Curie Point, Magnetic, Sharpness of the, Prof. N. F. Mott and Dr. H. H. Potter, 411
Cyclohexane, Isomerism of Derivatives of, R. D. Desai, Prof. R. F. Hunter and G. S. Saharia, 718
Debye Photographs, Layer-Line and, by means of the Characteristic X-Rays of the Crystal Itself, C. Finbak and Prof. O. Hassel, 194
Deductive and Inductive Methods in Science: a Reply, Dr. H. Dingle, 1011
Derris Roots, Histology of, Dr. R. R. Le G. Worsley and F. J. Nutman, 883
Deuterons, Slow, Induced Radioactivity of Silver with Neutrons from, E. Bertl, Prof. R. Furth, F. Obořil and Dr. K. Sitte, 964
1·1′-Diethyl-ψ-Cyanine Chloride, Molecular, Nematic and Crystal States of, Dr. E. E. Jelley, 631
Diffraction Experiments on the Resolving Power of Telescopes and Microscopes, Dr. K. B. Merling-Eisenberg, 416
Dimensions, The Theory of, Prof. G. W. O. Howe, 513
Diphenyl Compounds and Mammary Growth, Dr. G. A. Grant, 155
Diptera, The Ancestors of the, Dr. R. J. Tillyard, 66
Double Star Process, Another, Giving Very Fast Particles, Prof. H. Alfvén, 245
Droplets, Fog-, Cloud- and Rain-, Microscopic Examination of, N. Fuchs and I. Petsjanoff, 111
Drosophila Pupæ, Production of Local Depressions in the Development of, A. A. Wolsky, 1069
Dusts, Industrial, Certain, Some New Characteristic Properties, of Prof. H. V. A. Briscoe, P. F. Holt, J. W. Matthews and P. M. Sanderson, 753
E- and F_2-Layer, Annual Variation of the Critical Frequencies of the, L. Harang, 328
Earth and Moon, Figures of the, Dr. H. Jeffreys, 471
Earth's Magnetic Centre, Longitude Effect of Cosmic Radiation and the Position of the, Dr. M. S. Vallarta, 24
Eddy-Current Resistance in Fluids Due to Rotation, Prof. Kerr Grant, 673
Elasticity, Weight and, Perception of, Dr. D. Katz and W. Stephenson, 719
Electrical, Magnetic and, Dimensions, Sir James Henderson, Prof. G. W. O. Howe, 473; Sir James Henderson, 676; Prof. W. Cramp, 677; Prof. G. W. O. Howe; Prof. C. L. Fortescue, 844;
Electrodes used for Spectrographic Research, Latent Impurities in, D. A. Webb, 248; W. A. Roach, 547
Electro-Magnetic Waves along the Ground, Phase Velocity of, W. Ross and E. C. Slow, 671
Electron: Trajectories, Mechanical Tracer for, Dr. D. Gabor, 373; Inertia as the Cause of Harmonics in Valves, W. E. Benham, 591; Trajectories, Automatic Plotting of, D. B. Langmuir, 1066
Equilibrium and Kinetics in the Gaseous State and in Solution, Dr. G. A. Benford, Miss B. S. Khambata, and Dr. A. Wassermann, 669
Equivalent Particle-Observers, Prof. Leigh Page, 111
Ethylene Oxide, Thermal Decomposition of, Prof. M. W. Travers and C. G. Silcocks, 1018
Eucrangonyx gracilis, Occurrence of, Prof. W. M. Tattersall, 593
Fahrenheit's, Ole Rømer's and, Thermometers, Dr. Kirstine Meyer (née Bjerrum), 585; Dr. J. Newton Friend, 586
Fireflies in Jamaica, Flashing of, J. B. Buck, 801
Fire-Walking, H. Price, 928
Fishes, Fresh-water, Visual Purple System in, Dr. G. Wald, 1017
Flame Gases, Height of the Combustion Levels Attained in, Factors Influencing the, Prof. W. T. David, 289
Foam, Adsorption on, Dr. F. Schutz, 629
Fog-, Cloud- and Rain-Droplets, Microscopic Examination of, N. Fuchs and I. Petrjanoff, 111
Force Constants: and Structure, J. W. Linnett and Dr. H. W. Thompson, 509; and Molecular Structures, C. R. Bailey and J. B. Hale, 1112
Forestry, Students of, Instructional Tours for, Prof. R. S. Troup, 929
Fossil Pollen in Scottish Jurassic Coal, Dr. J. B. Simpson, 673
Fuels, Combustion of, Anti-Knocks and Pro-Knocks in the, A. V. Belov and Prof. M. B. Neumann, 798
Fumigants, Absorption of, under Reduced Pressure, Dr. A. B. P. Page and Dr. O. F. Lubatti, 553
Gamma: Ray Excitation by Fast Electrons, H. Aoki, 372; Rays Excited by Capture of Neutrons, J. H. E. Griffiths and Dr. L. Szilard, 323
γ-Rays, Absorption of, Measured by their Photo-effect in Beryllium, J. Rotblat, 963
Gaseous State, Equilibrium and Kinetics in the, and in Solution, Dr. G. A. Benford, Miss B. S. Khambata, and Dr. A. Wassermann, 669
Gases, Molecular Heats of, Temperature Drop Effect in Relation to the Determination of the, Prof. H. S. Gregory and R. W. B. Stephens, 28
Genetics in Madrid, Prof. J. B. S. Haldane, 331
Geodesics within Matter, Prof. J. L. Synge, 156
Geology in School Courses of General Science, Claims of, Prof. A. E. Trueman, 251; Dr. B. H. Knight, 329
Gesture Language, Sir Richard Paget, Bart., 198
Glucolysis without Phosphorylation in the Chick Embryo, Dr. J. Needham and H. Lehmann, 368
Gold Deuteride Bands, S. Imanishi, 591
Gottingen, The University of, J. D. Lambert, 930
Graphite Crystals, Abnormal Unidirectional Diamagnetism of, Temperature Variation of the, Prof. K. S. Krishnan and N. Ganguli, 155
Gravitation, The Constant of, Prof. E. A. Milne, 409
Growth-Ratio, Differential, Inheritance of a, Dr. E. Ashby and L. C. Luckwill, 71
Hæmochromogens, Coupled Oxidation of Ascorbic Acid and, Dr. R. Lemberg, B. Cortis-Jones and M. Norrie, 1016
Halogenobenzenes in the Gaseous Phase: Bromination of, Influence of Temperature and Catalysts on the Substitution Type, Prof. J. P. Wibaut and M. van Loon, 151
Harmonics in Valves, Electron Inertia as the Cause of, W. E. Benham, 591

Heavy: Ammonium Chloride, The Low-Temperature Transformation of, Prof. A. Smits and G. J. Muller, 804; Water, Electrolytic Separation of, An Effect of Rectified Current from a Tunger Valve upon the, T. Asada and E. Honde, 885

Helium: Liquid, Latent Heat of Evaporation of, Prof. J. Satterly; Dr. J. Newton Friend, 472; Chemical Detection of, Formed in Beryllium by Gamma Rays, Prof. F. A. Paneth and Dr. E. Glückauf, 712

Hexlet, The, Dr. F. Morley, 72; Prof. F. Soddy, 154; T. Gosset, 251; Prof. F. Soddy, 252

Histomonas meleagridis, Cultivation of, from the Liver Lesions of a Hen, Dr. H. P. Bayon and Dr. Ann Bishop, 370

Homo sapiens L., Lunar Periodicity in, Dr. D. L. Gunn, Penelope M. Jenkin and Dr. A. L. Gunn, 841

Human Malaria Parasites, A Presumptive Culicine Host of the, Prof. K. B. Williamson and Mahomed Zam, 714

Hume-Rothery Phases, β, The Existence-Range of the, M. Hara, 195

Hydrogen: Isotopes in Complex Cobaltammines, Interchange of, F. W. James, Dr. J. S. Anderson, and Prof. H. V. A. Briscoe, 109; and Hydroxyl Bonds, Isotope Effect in, Dr. J. M. Robertson and A. R. Ubbelohde, 504; Bridges, Synchronrized Oscillations in, Dr. M. L. Huggins, 550; Permeability of Metals to, Dr. C. J. Smithells, 1113

p-Hydroxy Propenyl Benzene (Anol), Œstrogenic Activity of, Prof. E. C. Dodds and W. Lawson, 1068

Hydroxyl, Hydrogen and, Bonds, Isotope Effect in, Dr. J. M. Robertson and A. R. Ubbelohde, 504

Ice-Water Relationships, a Method for Determining, by Measurements of Dielectric Constant Changes, L. T. Alexander and T. M. Shaw, 1109

Infra-Red Bands in the 3μ Region, Some, Dr. J. J. Fox and Dr. A. E. Martin, 507

Insect Life over the North Sea, Prof. A. C. Hardy and P. S. Milne, 510

Interstellar: Ionized Titanium, Spectrum of, Forbidden Transition in the, Dr. T. Dunham, jun., 246; Space? Molecules in, Prof. M. N. Saha, 840

Iodine: Oxides, Organic and Inorganic Chemistry of, Prof. I. Masson, 150; Compounds, Exchange Reactions of, H. A. C. McKay, 283

Ionization Constants of Organic Acids, Correlation of, with Dipole Moments, J. F. J. Dippy, 591

Ionosphere: Abnormalities of the, and Bright Solar Eruptions, R. Bureau, 110; Reflection from the, R. N. Rai, 115

Iron: Primary Oxide Film on, H. R. Nelson, 30; Passive, Examination of, by Electron Diffraction, I. Iitaka, S. Miyake and T. Iimori, 156; Inks in Antiquity, The Use of, The Lachish Letters and, A. Lewis, 470

Keratin Molecule, Constitution of the, Dr. J. B. Speakman and F. Townend, 411

Lachish Letters, The, and the Use of Iron Inks in Antiquity, A. Lewis, 470

Lanthanum, Supraconductivity of, Dr. K. Mendelssohn and J. G. Daunt, 473

Layer-Line and Debye Photographs by Means of the Characteristic X-Rays of the Crystal Itself, C. Finbak and Prof. O. Hassel, 194

Lead Extrusion Phenomenon, A. Dr. P. Dunsheath, 755; B. Jones, 1071

Lemna minor, Growth of, E. J. Winter, 1070

Light, Neutrino Theory of, Prof. E. C. G. Stueckelberg, 198; N. S. Nath, 331; A. Sokolow, 1071

Liquids, Acoustic Spectrum of, Sir C. V. Raman and B. V. Raghavendra Rao, 584

Locustana paradalina, Wing Abnormality in, Prof. T. F. Dreyer, 197

Luminous Efficiency of Rays Entering the Eye Pupil at Different Points, Dr. W. S. Stiles and B. H. Crawford, 246

Lyotropic Series and Free Energies, A Relation between the, Dr. L. H. N. Cooper, 284

McCormick and the Reaping Machine, Prof. J. Hendrick, 197

Magnetic: Effects Associated with Bright Solar Eruptions and Radio Fade-Outs, A. G. McNish, 244; and Electrical Dimensions, Sir James Henderson; Prof. G. W. O. Howe, 473; Sir James Henderson, 676; Prof. W. Cramp, 677; Prof. G. W. O. Howe; Prof. C. L. Fortescue, 844

Malaria Parasites, Life-Cycle of, New Knowledge of the, Lt.-Col. S. P. James and Dr. P. Tate, 545

Mammalian: Kidney, Structural Laws of the, with a Theoretical Derivation, Prof. E. J. Conway, 250; Gonad, Development *in vitro* of the, P. N. Martinovitch, 413

Mammary Growth, Diphenyl Compounds and, Dr. G. A. Grant, 155

Manganese Hydride, MnH, Band Spectrum of, Dr. R. W. B. Pearse and A. G. Gaydon, 590

Marine Cold-Blooded Animals in Different Latitudes, Rate of Tissue Metabolism of, Prof. H. Munro Fox and C. A. Wingfield, 369

Mating, Effect of Testosterone Propionate on, Dr. H. A. Shapiro, 588

Mercurialis perennis, Precise Distribution of, According to Soil Hydrogen Ion Concentration, J. F. Hope Simpson, 632

Mercury: Chloride (HgCl), Spectrum of, and Samuel's Theory of Linkage, Dr. K. Wieland, 590; Poisoning, Acute, in a Respiration Chamber, H. Christensen, M. Krogh, and M. Nielsen, 626; Vapour, Magnetic Susceptibility of, J. S. Shur, 804

Mesophyll in the Leaf, Wettability of the Cellulose Walls of the, Prof. D. H. Bangham and Prof. F. J. Lewis, 1107

Metal-Ammonia Ions, A Possible Acid-Dissociation of, and its Bearing on Certain Reactions, F. J. Garrick, 507; Dr. J. S. Anderson, N. L. Spoor, and Prof. H. V. A. Briscoe, 508

Metallic: Ions: on Films at Interfaces, Effects of Traces of, and on the Surface of Water, Dr. R. J. Myers and Prof. W. D. Harkins, 367; on Monolayers, Effects of Traces of, Dr. J. S. Mitchell, Prof. E. K. Rideal, and Dr. J. H. Schulman, 625; Dr. C. Robinson, 626; Films, The So-called 'Transition Temperature' of, T. Fukuroi, 884

Metals: Strain Energy in, Absorption of, N. A. de Bruyne, 633; Optical Constants of, A Photo-Electric Method for the Measurement of the, J. Bor, 716; Permeability of, to Hydrogen, Dr. C. J. Smithells, 1113

Meteorites and the Craters on the Moon, W. H. Steavenson, 968

Michelson-Morley Experiment, A Simple Means of Checking the, Prof. W. B. Cartmel, 110

Minerals, Rock-Forming, Hydrolysis of, Dr. A. Brammall and J. G. C. Leech, 754

Mite, Littoral, Biology of a, H. Madsen, 715

Molecular Structures, Force Constants and, C. R. Bailey and J. B. Hale, 1112

Molecules in Interstellar Space?, Prof. M. N. Saha, 840

Molluscs, Four, Rarely Recorded from the Red Sea, Dr. C. Crossland, 31

Molybdenum, Distortion and Yield Point of, P. Túry and S. Krausz, 30

Monodeuteroethylene, Raman Spectrum of, J. M. Delfosse, J. C. Jungers, G. Lemaitre, Y. L. Tchang and Prof. C. Manneback, 1111

Monolayers, Effects of Traces of Metallic Ions on, Dr. J. S. Mitchell, Prof. E. K. Rideal, and Dr. J. H. Schulman, 625; Dr. C. Robinson, 626

Moon: Earth and, Figures of the, Dr. H. Jeffreys, 471; Craters on the, Meteorites and the, W. H. Steavenson, 968

Museums and their Type Specimens, Dr. D. W. Lang, 191

Nature, Laws of, On the Origin of, Prof. E. A. Milne, 997

N_2+, Dissociation of, Dr. R. K. Asundi and Prof. R. Samuel, 375

Neon, Radioactive, Dr. T. Bjerge, 757

Neuroptera, Chromosome Behaviour and Phylogeny in the, H. Kingstedt, 468

Neutrino Theory: of Light, Prof. E. C. G. Stueckelberg, 198; N. S. N. Nath, 331; Relations in β-Ray Transformations and the, Dr. H. O. W. Richardson, 505; Of Light, A. Sokolow, 1071

Neutron, Disintegration of the, An Attempt to Detect the, C. W. Gilbert, C. L. Smith, and J. H. Fremlin, 796
Neutrons: Gamma Rays Excited by Capture of Neutrons, J. H. E. Griffiths and Dr. L. Szilard, 323; in Silver Nuclei, Resonance Levels of, C. Y. Chao and C. Y. Fu, 325; Free, Magnetic Moment of, A Method of Measuring the, Dr. O. R. Frisch, Dr. H. von Halban, jun., and J. Koch, 756; C-, Temperature Equilibrium of, Dr. O. R. Frisch, Dr. H von Halban, jun., and Dr. J. Koch, 922, Free, Sign of the Magnetic Moment of, Prof. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 1021; Fast, Artificial Radioactivity Produced by, and their Inelastic Collisions, J. Rotblat, 1110
Nickel Wire, Abnormally High Magnetic Permeability of, Obtained by Surface Treatment, Dr. T. F. Wall, 928
Nicotinic Acid and the Growth of *Staph. aureus*, B. C. J. G. Knight, 628
Nigeria and the Sahara, Dr. J. D. Falconer, 199
Nile, Dry Crossings of the, E. J. Wayland; Dr. H. E. Hurst, 961
Nitric Oxide: Reaction of, with Hæmoglobin and Methæmoglobin, Prof. D. Keilin and E. F. Hartree, 548; Inhibitions of Organic Decompositions by, Dr. H. W. Thompson and M. Meissner, 1018
Nitrogen: Active, Prof. J. Kaplan, 115; -Mercury Systems Excited by a-Rays, Action of Iron Oxide on the Emission Spectrum of, A. Luyckx, 672
North-East Land, Radio and Magnetic Observations at, During the Total Solar Eclipse of June 19, 1936, A. B. Whatman and R. A. Hamilton, 69
Œstrin Threshold, Cyclical Fluctuations in, Dr. S. Zuckerman, 628
Œstrogenic Agent, A Simple Aromatic, with an Activity of the Same Order as that of Œstrone, Prof. E. C. Dodds and W. Lawson, 627
'Optical Catalysers', Excitation of Raman Spectra with the Aid of, R. V. L. Hartley, 329
Orchestration, Adjustable Resonators and, Dr. E. G. Richardson, 157
Osphradium in the Gastropoda, A Possible Function of the, G. C. E. B. Hulbert and Prof. C. M. Yonge, 840
Ostrea edulis, Metamorphosis of the Larva of, H. A. Cole, 413
Ovalbumin in Urea Solvent, Dissociation of, Prof. J. W. Williams and Dr. C. C. Watson, 506
Ovarian Extracts, Androgenic Activity of, Dr. A. S. Parkes, 965
Ovulation, Experimental Induction of, with Progesterone, Dr. H. Zwarenstein, 112
Oxide Films on Copper and Iron, Measurements of, Dr. U. R. Evans and Dr. H. A. Miley, 283
Oxonium Compounds, Raman Spectra of, M. Wolkenstein and Prof. J. K. Syrkin, 288
Oxygen Evolved by Isolated Chloroplasts, R. Hill, 881
Oysters, English Native, *O. edulis*, Maturity and Fecundity of One-Year-Old, J. M. Dodd, J. McCloy, H. C. Davies, F. B. J. Edmonds, and Prof. J. H. Orton, 108
Panus stypicus (Bull.) Fries, Interfertility Phenomena of the American and European Forms of, Ruth Macrae, 674
Papain, Natural, Enzymic Properties of, M. Frankel, R. Maimin and B. Shapiro, 249
Particles, High-Speed, Specific Ionization by, M. G. E. Cosyns, 802
Peking Man, The Fifth Skull of, W. C. Pei, 109
Peptidase Activity, Dilatometric Ultra-Micro-Estimation of, Dr. K. Lunderstrøm-Lang, 713
Permanganates and Plant Growth, M. E. Webster and Dr. I. M. Robertson, 71
Peronospora Schleideniana W. G. Sm., 'Germination of Oospores of Onion Mildew, R. McKay, 758
Petroleum Lubricating Oils, Molecular Distillation of, R. Lyth, 374
Philosophy, Physical Science and, Sir Arthur Eddington, 1000; Prof. P. A. M. Dirac, 1001; Prof. W. H. McCrea, 1002; Prof. J. B. S. Haldane, 1003; Dr. H. Jeffreys, 1004; Dr. N. R. Campbell, 1005; Prof. L. N. G. Filon; Prof. W. Peddie; Prof. R. A. Sampson, 1006; Prof. C. G. Darwin, 1007; G. J. Whitrow, 1008; Fr. W. McEntegart; Dr. H. Stafford Hatfield; Prof. G. Dawes Hicks, 1009
Phospholipid Synthesis during Fat Absorption, C. Perrier M. Santangelo, C. Artom, G. Sarzana and Prof. S. Segrè, 1105
Phosphorescence of the Sea, Dr. R. E. D. Clark, 592; Dr. J. Weir French, 804
Phosphorus: Atoms in Plants and Seeds, Exchange of, Prof. G. Hevesy, Dr. K. Linderstrøm-Lang and C. Olsen, 149; in Animal Tissues, Rate of 'Organification' of, C. Artom, G. Sarzana, C. Perrier, M. Santangelo, and Prof. E. Segrè, 836; Metabolism in Normal Rachitic and 'Treated' Rats, Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and J. de Vries, 1068.
Physical: Constants and Some Curious Coincidences, Prof. J. Satterly, 290; Science and Philosophy, Sir Arthur Eddington, 1000; Prof. P. A. M. Dirac, 1001; Prof. W. H. McCrea, 1002; Prof. J. B. S. Haldane, 1003; Dr. H. Jeffreys, 1004; Dr. N. R. Campbell 1005; Prof. L. N. G. Filon; Prof. W. Peddie; Prof. R. A. Sampson, 1006; Prof. C. G. Darwin, 1007; G. J. Whitrow, 1008; Fr. W. McEntegart; Dr. H. Stafford Hatfield; Prof. G. Dawes Hicks, 1009
Phytophthora erythroseptica Pethybr., Asexual Fructifications by, Potassium Permanganate as an Aid to the Production of, R. McKay, 802
Picts? Who were the, Sir Herbert Maxwell, Bart., 115
Pike, Horizontal Semicircular Canal in the, Effect of Unilateral Elimination of the, Dr. O. Lowenstein, 715
Pisum sativum: Linkage in Structural Hybrids in, Miss Caroline Pellew, 113; Segmental Interchange Lines in, Mrs. E. Sansome, 113
Pituitary, Anterior, An Antiluteogenic Factor in the, J. Freud, 880
Planetary Positions at Sunset in 1937, S. L. Walkden, 471
Plankton Collector, The Modern Centrifugal Pump as a, S. G. Gibbons and J. H. Fraser, 417
Plant: Growth: Permanganates and, M. E. Webster and Dr. I. M. Robertson, 71; Hormones, Synthetic, E. M. Crook, Dr. W. Davies and Miss Norma Elizabeth Smith, 154; Collecting on the Pribilof and Aleutian Islands, 1936, Isobel W. Hutchison, 327; Virus, An Air-borne, Dr. Kenneth M. Smith, 370, Dr. J. Caldwell; Dr. Kenneth M. Smith, 761
Plastic Reconstruction, The Technique of, Dr. H. L. H H. Green, 759
Pollen Grains, Spontaneous Chromosome Changes in, Miss Margaret Upcott, 153
Positrons from Radio-Scandium, Dr. J. C. Jacobsen, 879
Potassium Permanganate as an Aid to the Production of Asexual Fructification by *Phytophthora erythroseptica* Pethybr., R. McKay, 802
Potato Virus: An *F*-Type, in Australia, J G. Bald, 674; 'Y', Acquired Immunity against the, Dr. R. N. Salaman, 924
Pregnancy Urine Extract, Inhibition of the Gonadotropic Activity of, by the Serum of Rabbits Injected with an Extract of Male Urine, P. de Fremery and B. Scheygrond, 1015
Progesterone: Experimental Induction of Ovulation with, Dr. H. Zwarenstein, 112; Effect of, on Lactation in the Rat, Dr. S. J. Folley and Dr. S. K. Kon, 1107
Protein 'Crystals' from Virus-Infected Plants, Structure Types of, Dr. J. D. Bernal and Dr. I. Fankuchen, 923
Proteins: Polarographic Effect of, in Cancer Diagnosis, Application of the, Dr. R. Brdička, 330; Nature of the Linkages in, Dr. Dorothy M. Wrinch, 718; Intramolecular Folding of, by Keto-Enol Interchange, Dr. W. T. Astbury and Dr. Dorothy M. Wrinch, 798
Proton-Neutron Exchange Interaction, Experimental Test of the, H. J. Bhabha, 1021.
Pseudo-Methæmoglobin, A New Blood Pigment, Dr. N. H. Fairley, 588
Puccinia graminis, Production of Uredia and Telia of, on *Berberis vulgaris*, Dr. Margaret Newton and Dr. T. Johnson, 800
Purple, Visual: Scotopic Luminosity Curve and the Absorption Spectrum of, Dr. H. J. A. Dartnall and C. F. Goodeve, 409; Bleaching of, in Solution, Dr. G. Wald, 587
Racial Theory and Cross-Breeding, A. M. Hocart, 415

Radiation, Colloids and the Biological Effect of, R. T. M. Haines, 32

Radiation, A Photochemical Antagonism of, G. Holst, 285

Radio: -active Disintegration of a Light Element, α-Particles from the, Dr. W. B. Lewis, W. E. Burcham and W. Y. Chang, 24; Waves, Interaction by Resonance of, Prof. V. A. Bailey, 68; Fade-Outs, Bright Solar Eruptions and, Magnetic Effects Associated with, A. G. McNish, 244; -activity, Induced, with Neutrons from Slow Deuterons, E. Bertl, Prof. R. Furth, F. Obořil, and Dr. K. Sitte, 716; -active Substances, Thermal Precipitation of, Prof. F. A. Paneth and Dr. C. Rosenblum, 796; Isotopes of Copper, Dr. E. A. Oeser and J. L. Tuck, 1110; Waves, Resonance in the Interaction of, Prof. V. A. Bailey, 838; -activity Induced by Fast Neutrons According to the $(n, 2n)$ Reaction, F. A. Heyn, 842; Produced by Gamma Rays and Neutrons of High Energy, W. Y. Chang, M. Goldhaber and R. Sagane, 962; Induced, of Silver with Neutrons from Slow Deuterons, E. Bertl, Prof. R. Fürth, F. Obořil and Dr. K. Sitte, 964; Artificial, Produced by Fast Neutrons and their Inelastic Collisions, J. Rotblat, 1110; -Scandium, Positrons from, Dr. J. C. Jacobsen, 879

Radium Rays, Action of, on the Growth of Cells *in vitro*, Prof. L. Halberstadter and L. Doljanski, 841

Rainfall and Moon Phases in the Tropics, C. H. B. Williams, 244

Raman: Spectrum of Benzene Vapour, S. Bhagavantam and Dr. A. V. Rao, 114; Spectra: of Oxonium Compounds, M. Wolkenstein and Prof. J. K. Syrkin, 288; Excitation of, with the Aid of 'Optical Catalysers', R. V. L. Hartley, 329; Effect as a Method of Analysis of Amino Acid Solutions, N. Wright and W. C. Lee, 551; Spectrum of Monodeuteroethylene, J. M. Delfosse, J. C. Jungers, G. Lemaitre, Y. L. Tchang and Prof. C. Manneback, 1111

Ranikot Sea, Extent of the, Lieut.-Col. L. M. Davies, 414

Rare Earths, Bivalent, Fluorescence of the, Prof. K. Przibram, 329

Rat, Lactation in the, Effect of Progesterone on, Dr. S. J. Folley and Dr S. K. Kon, 1107

Rats, Normal, Rachitic and 'Treated', Phosphorus Metabolism in, Dr. M. J. L. Dols, Prof. B. C. P Jansen, Prof. G. J. Sizoo and J. de Vries, 1068

Rays Entering the Eye Pupil at Different Points, Luminous Efficiency of, Dr. W. S. Stiles and B. H. Crawford, 246

Realgar in Wookey Hole, Somerset, Dr. J. Newton Friend, 72

Reaping Machine, McCormick and the, Prof. J. Hendrick, 197

Red Sea, Four Molluscs rarely recorded from the, Dr. C. Crossland, 31

Resolving Power, Effect of the Penetration of X-Rays on the, Prof. V. Dolejšek and J. Klein, 886

Resonators, Adjustable, and Orchestration, Dr. E. G. Richardson, 157

Retinal Centre as an Amplifier of Potential Differences, The, Prof. R. Granit, 719

Retinitis Pigmentosa, Carotene Therapy of, Dr. E. M. Josephson and Dr. M. Freiberger, 155

Rice, Dwarfing in, Genes for, B. S. Kadam, 1070

Rømer's, Ole, and Fahrenheit's Thermometers, Dr. Kirstine Meyer (née Bjerrum), 585; Dr. J. Newton Friend, 586

Root: Nodules, Leguminous, Excretion from, Dr. G. Bond, 675; -Growth in the Soil, A Device for the Observation of, Dr. G. H. Bates, 966

Rous Fowl Sarcoma, Nature of the Causative Agent of the, Prof. E. M. Fraenkel and Dr. C. A. Mawson, 282

Rubbing Solids, Surface Temperature of, and the Formation of the Beilby Layer, Dr. F. P. Bowden and T. G. Hughes, 152

Sahara, Nigeria and the, Dr. J. D. Falconer, 199

Samuel's Theory of Linkage, Spectrum of Mercury Chloride (HgCl) and, Dr. K. Wieland, 590

Saprophytic Flagellatæ, Assimilation of Different Organic Substances by, Prof. E. G. Pringsheim, 196

Science: Deductive and Inductive Methods in, a Reply, Dr. H. Dingle, 1011

Scientific: Worthies and Events Commemorated on Postage Stamps, J. G. Pilkington, 331; Research in Spain, Prof. C. S. Gibson, 719

Seeber, Dr., in South Africa, K. H. Barnard, 474

Selaginella, Correlation Phenomena and Hormones in, Dr. S. Williams, 966

Sheep: Hookworm, Attachment of the, to the Common Sheep Tapeworm, D. G. Davey, 250; Tapeworm, Common, Attachment of the Sheep Hookworm to the, D. G. Davey, 250

Silica, Fused, The 2 73μ Absorption Band of, Dr. J. W. Ellis and Dr. W. K. Lyon; Dr. D. G. Drummond, 70

Silicon Pentoxide (Si_2O_5), Two-Dimensional Crystals of, N. A. Shishacow, 927

Silver Haloids, The Dependence of the Thermal Expansion Coefficients of, on Temperature, P. G. Strelkov, 803

Sittannavasal, Cave Temple at, Technique of the Painting Process in the, S. Paramasivan, 114

Smith, Sir Grafton Elliot, and Work on Early Man in China, W. C. Pei, 192

Soils, Base Exchange Capacity and Clay Content of, Dr. R. L. Mitchell and Dr. A. Muir, 552

Solar: Corona, Some Polarization Data of the, Dr. W. M. Cohn, 29; Eruptions, Bright: Abnormalities of the Ionosphere and, R. Bureau, 110; and Radio Fade-Outs, Magnetic Effects Associated with, A. G. NcNish, 244; Eclipse of December 13–14, 1936, Fall of Air Temperature during the, R. C. Hayes, 967

Sound: Propagation of, Effect of Turbulence on the, H. Dahl and Dr. O. Devik, 550; Velocity in Liquids, Dispersion of, B. V. Raghavendra Rao, 885

Spain, Scientific Research in, Prof. C. S. Gibson, 719

Spectrographic Research, Sources of Inaccuracies in, Dr. E. J. B. Willey, 758

Spoon Gauge, A Sensitive Adaptation of the, A. Lewis and Dr. D. W. G. Style, 631

Staph. aureus, Nicotinic Acid and the Growth of, B. C. J. G. Knight, 628

Starlings, London, Effects of Traffic Disturbance and Night Illumination on, Prof. W. Rowan, 668

Static Electricity on the Surface of Solid Dielectrics, Origin of, J. Strachan, 803

Sterckfontein Ape, The, Dr. R. Broom, 326

Stick Insects, Feeding Habits of, H. J. Sargent, 156

Stimulating Materials Obtained from Injured and Killed Cells, J. C. Fardon, R. J. Norris, Prof. J. R. Loofbourow, and Sister M. Veronita Ruddy, 589

Sun, Magnetic Moment of the, Cosmic Rays and the, Dr. M. S. Vallarta, 839

Supraconducting Sphere in the Intermediate State, Electrical Conductivity of a, L. Shubnikov and I. Nakhutin, 589

Supraconductors of Small Dimensions, R. B. Pontius, 1065

Swammerdam, Jan, Prof. F. J. Cole, 287

Symbols, Symmetry of, Prof. S. Goudsmit, 417

Tantalum, A New Phenomenon in the Supraconducting Transition of, and of Tin, Dr. F. B. Silsbee, R. B. Scott, and Dr. F. G. Brickwedde, 325

Terbium Salts, Luminescence of Solutions of, A. Seidel, 248

Testosterone Propionate, Effect of on Mating, Dr. H. A. Shapiro, 588

Tetrachorethylene, Potential Constants of, J. Duchesne, 288; 634

Thermometry, Resistance, Below 1·0° K., Dr. J. F. Allen and E. S. Shire, 878

Thyroid, Effect of Vitamin E Deficiency on the, Miss M. M. O. Barrie, 286

Timbers from Tropical and North Temperate Regions, A Comparison of Certain Properties of, S. H. Clarke, 511

Tin · A New Phenomenon in the Supraconducting Transition of Tantalum and of, Dr. F. B. Silsbee, R. B. Scott, and Dr. F. G. Brickwedde, 325; Influence of Magnetic Fields on Persistent Currents in Supraconducting Single Crystals of, Prof. E. F. Burton and K. C. Mann, 325

Tissue Metabolism of Marine Cold-Blodded Animals in Different Latitudes, Rate of, Prof. H. Munro Fox and C. A. Wingfield, 369
Titanium, Interstellar Ionized, Forbidden Transition in the Spectrum of, Dr. T. Dunham, jun., 246
Tobacco Mosaic Virus, Visible Mesomorphic Fibres of, in Juice from Diseased Plants, R. J. Best, 628
Toepler *Schlieren* Method, Observation of Ultracentrifugal Sedimentation by the, A. Tiselius, K. O. Pedersen and Inga-Britta Eriksson-Quensel, 546
Tops, Simplest Air-driven, Sedimentation Equilibrium in the, Prof. J. W. McBain and C. Alvarez-Tostado, 1066
Total Solar Eclipse of June 19, 1936, Radio and Magnetic Observations at North-East Land during the, A. B. Whatman and R. A. Hamilton, 69
S-Trideuterobenzene and the Structure of Benzene, C. R. Bailey, A. P. Best, P. R. Gordon, J. B. Hale, Prof. C. K. Ingold, A. H. Leckie, L. H. P. Weldon, and C. L. Wilson, 880
Tropics, Rainfall and Moon Phases in the, C. H. B. Williams, 244
Tsetse Flies, Water and Fat Contents of, R. W. Jack, 31; Dr. C. H. N. Jackson, 674; Dr. K. Mellanby, 883
Tyrosine in Diseased Pedipalps, F. A. Bannister, 469
Ultra-centrifugal Sedimentation, Observation of, by the Toepler *Schlieren* Method, A. Tiselius, K. O. Pedersen and Inga-Britta Eriksson-Quensel, 546
Ultra-High-Frequency Currents in Long Antennæ, Distribution of, Prof. L. S. Palmer and K. G. Gillard, 967
Upper Atmosphere: Ionization of the, Effect of Meteoric Shower on the, J. N. Bhar, 470; Pressures in the, Measurement of, Prof. J. Kaplan, 1112
Urea as a Hygroscopic Substance, Prof. E. A. Werner, 512
Vaccinia Virus, Inactivation of, by Ascorbic Acid and Glutathione, I. J. Kligler and H. Bernkopf, 965
Vacuoles, Contractile, Mechanism of the Diastole of, Dr. J. A. Kitching, 70
Vacuum Photo-Cell, Time Lag of the, Dr. R. A. Houstoun, 29; Dr. N. R. Campbell, 330
Viruses Organisms or Autocatalysts? Are, Prof. H. H. Dixon, 153
Viscum album, Effects of Colchicin and of, Preparations upon Germination of Seeds and Growth of Seedlings, L. Havas, 371
Visual Purple System in Fresh-water Fishes, Dr. G. Wald, 1017
Vitamin: E Deficiency, Effect of, on the Thyroid, Miss M. M. O. Barrie, 286; P., A. Bentsáth, S. Rusznyák, and Prof. A. Szent-Györgyi, 326; A, Estimation of, Miss E. M. Hume, 467; C: Duality of the Reversibly Oxidized Forms of, and the Polarization of its Dienol Group, Prof. N. Bezssonoff and M. Woloszyn, 469; in the Living Organism, Determination of, Dr. H. Rotter, 717
Warburg's Co-Ferment, Correlation of the Yellow Oxidation Ferment with, Prof. J. Kenner, 25
Weight and Elasticity, Perception of, Dr. D. Katz and W. Stephenson, 719
Whale Shark Rammed by a Steamer off Colombo, Ceylon, A, Dr. E. W. Gudger, 549
Wind, Variation of, with Height, Sir Napier Shaw, 926
Wood-boring Insects, Protein Digestion of, H. S. Hopf, 286
Woody Cuttings, Growth Substances, Root Production, and Cambial Activity in, Dr. M. A. H. Tincker, 1104
Wookey Hole, Somerset, Realgar in, Dr. J. Newton Friend, 72
Wool Growth, Gradients in, Dr. A. B. Wildman, 285
X-Rays: A Condensing Monochromator for, Dr. I. Fankuchen, 193; Penetration of, Effect of the, on the Resolving Power, Prof. V. Dolejšek and J. Klein, 886
Yeast, Alcohol Apo-dehydrogenase from, Preparation of a Highly Active, M. Sreenivasaya, 112
Yellow Oxidation Ferment, Correlation of the, with Warburg's Co-ferment, Prof. J. Kenner, 25
Zinc and Cadmium near the Melting Point, Anomalous Expansion of, W. F. Hachkovsky and P. G. Strelkov, 715
Corrosion: Biological and Bacteriological Aspects of, R. Legendre, 891; Monaco Conference on, 891; of a Low Alloy Chromium-Aluminium Steel Exposed to Sea Air, etc., Prof. A. M. Portevin and Dr. E. Herzog, 892; of Magnesium and Non-protected Ultra-light Alloys, Methods of Testing by, J. Cournot and Mlle. Louise Halm, 1081
Corticosteron: a Crystallized Compound with the Biological Activity of the Adrenal-Cortical Hormone, P. de Fremery, E. Laqueur, Prof. T. Reichstein, R. W. Spanhoff, and I. E. Uyldert, 26; in the Glucose Test in Rats, Activity of, Prof. T. Reichstein, Prof. F. Verzár, and L. Laszt, 331
Cosmetic Dermatology: with Dictionary of Ingredients, etc., Dr. H. Goodman (*Review*), 457
Cosmic: Radiation, Longitude Effect of, and the Position of the Earth's Magnetic Centre, Dr. M. S. Vallarta, 24; Showers, Passage of Fast Electrons and the Theory of, H. J. Bhabha and W. Heitler, 299; Radiations, Negative Protons in, H. J. Bhabha, 415; Data, Broadcasting of, 582; Rays, Effect of Temperature on, J. Priebsch and H. Kramer, 603; Ray: Shower, Diurnal Variation of, Dr. M. Forró, 633; Showers, Y. Watase, 671; Rays and the Magnetic Moment of the Sun, Dr. M. S. Vallarta, 839; Radiation, Origin of the, H. Alfvén, 938; Rays: Origin of, Dr. M. C. Holmes, 971; Sidereal Time Periodicity of, and its Phase Shift, Dr. J. Barnóthy and Dr. M. Forró, 1064
Cosmological Constants, The, Prof. P. A. M. Dirac, 323; Dr. S. Chandrasekhar, 757
Cotton: Resistance of, to the Wilt Fungus, Dr. B. B. Mundkur, 293; Growing Research, 501; Cytology and Genetics of, Dr. A. Skovsted; Dr. S. C. Harland, 1074
Couleurs, Code universel des, E. Séguy (*Review*), 530
Couples (Neutron-Neutrino), Wave Mechanics of, Prof. Max Born, 68
Coventry, Scientific Association of, 279
Crayfordian and Boltonian Industries, The, J. Reid Moir and J. P. T. Burchell, 676
Cretaceous, Lower, A New Sheet of, at Voirons (Préalpes externes, Haute-Savoie), A. Lombard, 855
Crinoidea of the John Murray Expedition, A. H. Clark, 888
Crop Production, Effect of Oxidizing Agents on, Prof. V. Subrahmanyan, C. R. Harihara Iyer, and R. Rajagopalan, 595
Cross-Cousin, Marriage in Assam, Origin of, Prof. J. K. Bose, 328
Crossing-Over and Chiasmata, Dr. K. Mather, 33
Croydon Natural History and Scientific Society: Regional Survey Atlas of Croydon and District (*Review*), 394
Crystal: Analysis, Development of, Sir William Bragg (Sir Henry Trueman Wood lecture), 104; Structure, Mineralogical Problems of, Prof. P. Niggli, 255; Polymorphism, The Kinetic Basis of, M. J. Buerger, 481
Crystallized Compound, Partial Synthesis of a, with the Biological Activity of the Adrenal-Cortical Hormone, Marguerite Steiger and Prof. T. Reichstein, 925
Crystallography: Recent Work in, Sir William Bragg, 228; Recent, Sir William Bragg, 865
Crystals: Graphite, Abnormal Unidirectional Diamagnetism of, Temperature Variation of the, Prof. K. S. Krishnan and N. Ganguli, 155; Magnetic and Optical Properties of, Prof. K. S. Krishnan, 810
Cucumber: Viruses 3 and 4, Liquid Crystalline Preparations of, F. C. Bawden and N. W. Pirie, 546; Metabolism and Growth-Responses of the, Dr. R. B. Dearborn, 847
Cucurbitaceæ in Egypt, Powdery Mildew of, Dr. A. Fikry, 847
Culture Fluids, Buffer Action in, F. Chodat and R. Cortesi, 1031
Culturologia, Epitome de, Dr. Imbelloni (*Review*), 310
Curie Point, Magnetic, Sharpness of the, Prof. N. F. Mott and Dr. H. H. Potter, 411

Curie's, Mme., Swan Song, Prof. F. Soddy (*Review*), 528
Cyclists, Tracks for, 241
Cyclohexane: Isomerism of Derivatives of, R. D. Desai, Prof. R. F. Hunter and G. S. Saharia, 718; and Benzene, Dielectric Constants of, Mlle. Jacqueline Hadamard, 1030
Cyclol Theory, The, and the 'Globular' Proteins, Dr. D. M. Wrinch, 972
Czechoslovak National Research Council, 794

Dalton on the Constitution of the Atmosphere [1837], 1029
Darwin: Charles: Works of, in Russian, 622; and the Modern Theory of Tropisms, Prof. N. Cholodny, 919; on Coral Formations [1837], 937
Darwin's Gifts to the Zoological Society [1837], 81
Davenport's Invention of an Electric Motor [1837], 341
Days: My Fill of, Sir Peter Chalmers Mitchell (*Review*), 347; The Fullness of (*Review*), 347
Debye Photographs, Layer-Line and, by Means of the Characteristic X-Rays of the Crystal Itself, C. Finbak and Prof. O. Hassel, 194
Deciduous Fruit, Studies in, I. Donen (4, 5), 167
Defence that is No Defence, Dr. C. E. M. Joad, 364
Derris Roots, Histology of, Dr. R. R. Le G. Worsley and F. J. Nutman, 883
Desgenettes, Baron (1762–1837), 207
Detergent Action, Wetting and, 423
Detonation of an Explosive, Photographs of Phenomena Accompanying the, Taken at Intervals of 0·00001 sec., A Michel-Lévy and H. Muraour, 602
Detroit, A Traffic Clinic set up in, 1063
Deuterons, Slow, Induced Radioactivity of Silver with Neutrons from, E. Bertl, Prof. R. Fürth, F. Obořil and Dr. K. Sitte, 964
Deuterium: Content of Normal Water, J. L. Gabbard and M. Dole, 293; Water, Solubilities in, R. W. Shearman and A. W. C. Menzies, 335; Photosensitized Reactions Involving, Prof. H. S. Taylor and others, 933; Atomic, Reactions of, with Paraffin Hydrocarbons, Taylor, 971
Development Commission, Twenty-sixth Report, 681
Diamantine Compounds, Dr. O. Bottger, 555
Dichloracetic Ester, Condensation of, with Ketones and Aldehydes by the Use of Very Dilute Metallic Amalgams, G. Darzens, 125
Diesel: Engines: Excessive Lubricating Oil Consumption, P. H. Smith (*Review*), 174; and other Internal-Combustion Engines, Prof. H. E. Degler (*Review*), 174; Engineering, Elements of, O. Adams (*Review*), 174; Mine Locomotives—Development and Use in European Coal Mines, 622
1:1′-Diethyl-ψ-Cyanine Chloride, Molecular, Nematic and Crystal States of, Dr. E. E. Jelley, 631
Diethylether, Inflammation of, Influence of Nitrogen on the, J. Baron and P. Laffitte, 686
Diffraction Experiments on the Resolving Power of Telescopes and Microscopes, Dr. K. B. Merling-Eisenberg, 416
Diffusion, Equation of, P. S. Epstein, 729
Digestive Tract: The, a Radiological Study of its Anatomy, Physiology and Pathology, Dr. A. E. Barclay. Second edition (*Review*), 463
Dimensions: The Theory of: Prof. G. W. O. Howe (*Review*), 45; and its Application for Engineers, Dr. F. W. Lanchester (*Review*), 45; Prof. G. W. O. Howe, 513
Diphenyl Compounds and Mammary Growth, Dr. G. A. Grant, 155
Dipnoan Fish, a New Long-headed, from the Upper Devonian of Scaumenac Bay, P.Q., Canada, W. Graham-Smith and T. S. Westoll, 976
Diptera, The Ancestors of the, Dr. R. J. Tillyard, 66
Dirac's Equations, Geometry of, and their Expression in Tensor Form, H. S. Ruse, 259
Discovery II, R.R.S. Survey Party, 147
Disease Resistance in Plants, 598
Diseases: Old, and New, Lord Horder, 571; General Registration of, [1837], 937
Distillation with Simultaneous Expansion of Vapours, W. Swietosławski and E. Ramotowski, 729
Diurnal Magnetic Variations, Zonal Discordance in, E. H. Booth, 523
Divinylglycol: Catalytic and Acid Dehydration of, E. Urion and E. Baum, 602; Dehydration of, by Sulphuric Acid, M. Tiffenau and P. Weill, 602
Doctor's Odyssey: A, Adventures in Forty-five Countries Dr. V. Heiser (*Review*), 732
Donne, John: and the New Philosophy, Prof. C. M. Coffin (*Review*), 1035; Science and, (*Review*), 1035
Double Star Process, Another, Giving Very Fast Particles, Prof. H. Alfvén, 245
Douglas's, David, Observations in America, [1837], 685
Dowser: the Modern, A Guide to the Use of the Divining Rod and Pendulum, Le Vicomte Henry de France. Translated by A. H. Bell (*Review*), 352
Droplets, Fog-, Cloud- and Rain-, Microscopic Examination of, N. Fuchs and I. Petrjanoff, 111
Drosophila: Ovarian Rhythm in, H. P. Donald and Miss Rowena Lamy, 40; *melanogaster*: Relations between Chromosome Size and Effects of inversions on Crossing-Over in, A. G. Steinberg, 729; Chromosomal Deficiencies and the Embryonic Development of, D. F. Poulson, 897; Development of Eye Colours in, K. V. Thimann and G. W. Beadle, 897; Pupæ, Production of Local Depressions in the Development of, A. A. Wolsky, 1069
Dubois, Baron Antoine (1756–1837], 559
Ducks, Hybrid, Genetics and Cytology of, Prof. F. A. E. Crew and Dr. P. C. Koller, 117
D'Urville's Dumont, Voyage in the *Astrolabe* [1837], 521
Dusts, Certain Industrial, Some New Characteristic Properties of, Prof. H. V. A. Briscoe, P. F. Holt, J. W. Matthews, and P. M. Sanderson, 753

E and F_2-Layers, Annual Variation of the Critical Frequencies of the, L. Harang, 328
Early Man: in Java, Dr. P. V. van Stein Callenfels, 294; in Japan, Prof. S. Tokunaga, 502
Earth: Constitution of the, J. H. Reynolds, 314; and Moon, Figures of the, Dr. H. Jeffreys, 381; 471
Earth's Magnetic Centre, Longitude Effect of Cosmic Radiation and the position of the, Dr. M. S. Vallarta, 24
Earthquake: Salvador, of December 20, 19; in Kent on December 29, 64; Tibet, of January 7, 106; Research Institute of Japan, The, Dr. C. Davison, 615; on June 21, 1103
Earthquakes: Great, Dr. C. Davison (*Review*), 176; Recent, at Helena (Montana), F. P. Ulrich, 378; in New Zealand, Dr. J. Henderson and R. C. Hayes, 420; Deep-focus, Geographical Distribution of, B. Gutenberg and C. F. Richter, 476; N. H. Heck (*Review*), 529; in India, W. D. West, 639; Destructive, Distribution of, U. Vanni, 933; Deep-focus, Distribution of, S. Yamaguti, 1074; in India, W. D. West, 1118
East African: Plateaux and Rift Valleys, Prof. Bailey Willis, 339; Rift Valleys, W. C. Simmons, 339
Ebulliometry, Prof. W. Świetosławski (*Review*), 532
Eclipse: Photography, Natural Colour, Dr. I. C. Gardner, 434; Broadcasting an, 917
Eclipsing Binaries, Internal Constitution of, Z. Kopal, 293
Eddy-Current resistance in Fluids due to Rotation, Prof. Kerr Grant, 673
Edinburgh University: award of the Cameron prize to Prof. J. B. Collip; grant from the University Grants Committee, 299; of, Physical Science in the [1837], 479
Education: in England and Wales, F. B. Stead, 296; for those out of School, 581
Egyptian Mummies [1837], 601
Eichholz Clinic, Medical Board of the, Sir Humphry Rolleston appointed chairman of the, 710
Einstein System, Geometry of the Rotating Disk in the, P. Dive, 977

Eisen- und Stahllegierungen: Patentsammlung Erganzungsheft I, A. Grutzner (*Review*), 310

Elastic Deformations, Finite, F. D. Murnaghan, 1074

Electric: Locomotives for the Natal Railways, 709; Eel, The, C. W. Coates and R. T. Cox, 970

Electrical: Supply in Great Britain, 127; Laboratory Experiments—Theory and Practice: being an abridgement of "Experimental Electrical Engineering", Prof. V. Karapetoff. Arranged and revised by Prof. B. C. Dennison (*Review*), 134; Engineers, Institution of, Dr. A. Russell elected an honorary member; award of the Faraday medal to Prof. A. Blondel, 189; Magnetic and Dimensions, Sir James Henderson; Prof. G. W. O. Howe, 473; Sir James Henderson, 676; Prof. W. Cramp, 677; Industry of the World, 832; Engineers, Institution of, Premium awards, 834; Magnetic and, Dimensions, Prof. G. W. O. Howe; Prof. C. L. Fortesque, 844; Society of London [1837], 853; Measurements, Fundamental (*Review*), 1038; Precise Comparisons of Standards and Absolute Determinations of the Units, Dr. H. L. Curtis (*Review*), 1038; Engineers' Handbook, 4: Electic Power, under the editorship of Dr. H. Pender, W. A. Del Mar and K. McIlwain. Third edition (*Review*), 1039

Electricity: Commissioners, Sixteenth Annual Report of the, 1st April 1935 to 31st March 1936, 127; Properties of [1837], 258; and Magnetism, Advanced Laboratory Practice in, Dr. E M. Terry, revised by Prof. H. B. Wahlin. Third edition (*Review*), 393; Supply in Great Britain, 440; Costs and Factors, J. A. Sumner, 501, Supply Tariffs, J. F. M. Mellor, 580; in Mining, Prof. W. M. Thornton, 596; Weight and, Perception of, Dr D Katz and W. Stephenson, 719; in the Hospital, R. S. Whipple (Faraday lecture), 876; Meters, Integrating, G. F. Shotter, 890; Technical, H. T. Davidge and R. W. Hutchinson. Fifth edition (*Review*), 947; in Solids, Conduction of, Prof. N. F. Mott; 951; in France, Transmission of, P. M J. Ailleret, 1049; Meters, Prepayment, J. Prince and M. Whitehead, 1102

Elektrizitätslehre, Einführung in die, Prof. R. W. Pohl. Vierte Auflage (*Review*), 864

Electrode Potential of Tin Films of Zinc on Platinum, D. P. Mellor and H. Mulhall, 522

Electrodeposition Conference, The First International, 808

Electrodes used for Spectrographic Research, Latent Impurities in, D. A. Webb, 248; W. A. Roach, 547

Electrolytic Deposits: Structure of, P. Jacquet, 644; Value of the microscopic method for the study of, P. Jacquet, 1081

Electrolysis with a Mercury Cathode, O. Dony-Hénault and A. de Jaer, 938

Electro-Magnetic Waves along the Ground, Phase Velocity of, W. Ross and E. C. Slow, 671

Electron: The, its Intellectual and Social Significance, Dr. K. T. Compton, 202; 226, 229; Theory of Metals (*Review*), 348; Trajectories, Mechanical Tracer for, Dr. D. Gabor, 373; Inertia as the cause of Harmonics in Valves, W. E. Benham, 591; Trajectories, Automatic Plotting of, D. B. Langmuir, 1066

Elektrodynamik, klassische, Einfuhrung in die, Dr. J. Fischer (*Review*), 947

Embryology, Experimental, Dr. G. R. de Beer (*Review*), 982

Empire: Botany, Kew's contribution to, 850; Agricultural Officers, Annual Gathering, 1028; Cotton Growing Corporation, 1048

Employment of Young Persons, Hours of, 662

Engineers, British, abroad and their Prospects, 563

Engineer's Year-Book of Formulæ, Rules, Tables, Data and Memoranda for 1937. 43rd Annual issue, revised under the direction of L. St. L. Pendred (*Review*), 906

England: Rural, at the Royal Academy, Dr. Vaughan Cornish, 786; and Wales, Population of [1837], 853; The Scenic Heritage of, Dr. O. J. R. Howarth (*Review*), 945

English: Life, Political and Social, A History of, Mrs. Amabel Williams-Ellis and F. J. Fisher (*Review*), 308; Place-Names, The Concise Oxford Dictionary of, Dr. E. Ekwall (*Review*), 445; Terms in Scientific Writings, 578

Environment: Heredity *versus*, Dr. D. Forsyth, 768; and Nation: Geographical Factors in the Cultural and Political History of Europe, Prof. Griffith Taylor (*Review*), 390

Episternal Bones in Man, W. M. Cobb, 846

Equilibrium and Kinetics in the Gaseous state and in Solution, Dr. G. A. Benford, Miss B. S. Khambata and Dr. A. Wassermann, 669

Equivalent Particle-Observers, Prof. Leigh Page, 111

Erebia, Monograph of the genus, B. C. S. Warren (*Review*), 265

Ericsson's, John, Screw Propeller [1837], 895

Erysiphaceæ of Japan, Yasu Homma, 1115

Escherichia communior found as a Contaminating Organism in 'Starter', L. O'Droma and M. Grimes, 728

Essential Oils: Chemistry of, Prof. J. Reid (Streatfeild memorial lecture), 80, in Plants, Secretions of, Prof. J. Politis, 379

Essex: Coast, Submerged Archæological Sites on the, 200; South-East, Technical College, 556

Ethyl Alcohol in Marine Animals, Diffusion of, and the hypothesis of Combined Water, M. Nicloux, 728

Ethylene Oxide, Thermal decomposition of, Prof. M W. Travers and C. G. Silcocks, 1018

Eucalyptus radiata (*E. numerosa*), Occurrence of a number of varieties of, as determined by Chemical Analyses of the Essential Oils, A. R. Penfold and F. R. Morrison (2), 603

Eucrangonyx gracilis, Occurrence of, Prof. W. M. Tattersall, 593

Eugenics Society, appointment of a Population Investigation Committee, 1063

Euphrates Expedition, End of the [1837], 895

Europe, North-Western, Zoogeographical History of, P. Ullyott, 186

Evaporation records in the Netherlands, D. C. Braak, 970

Evolution, Quantitative (2), J. Small, 976

Exanthemata: Acute, The History of the, Dr. J. D. Rolleston (*Review*), 1037; Infectious (*Review*), 1037

Exhibition of 1851, Royal Commission of Overseas Scholarships, 437

Experimentelle Beitrage zu einer Theorie der Entwicklung, Prof. H. Spemann (*Review*), 982

Extrafoveal Vision, Effect of Glaring Light Source on, Dr. W. S. Stiles and B. H. Crawford, 259

Fahrenheit's: Thermometric Scale, The Origin of, Dr. J. Newton Friend, 395; Ole Rømer's and, Thermometers, Dr. Kirstine Meyer (née Bjerrum), 585; Dr. J. Newton Friend, 586

Faraday: on the views of Prof. Mossotti [1837], 124; on Marshall Hall [1837], 341

Farish, Rev. William, death of [1837], 81

Farm Animals, Diseases of, Research on, 1100

Farming: Mechanized: Conference on, 164; Discussions on, 1048

Faune de France, 30: Cestodes, Prof. C. Joyeux et Dr. J. G. Baer (*Review*), 611

Fermente, Die, und ihre Wirkungen, Prof. C. Oppenheimer. Suppt. Lief. 5 (*Review*), 50

Ferret, Development of the, Early stages in the, W. J. Hamilton, 976

Ferromagnetic: Bodies at the Curie Point, Variation of the Catalytic power of, H. Forestier and R. Lille, 385; Oxides at the Curie Point, variation of catalytic activity of, H. Forestier and R. Lille, 1030

Feulgen's Stain, Euchromocentre type of Nucleus and, G. Yamaha and S. Suematsu, 889

Film Music: a Summary of the characteristic features of its History, Aesthetics, Technique; and possible Developments, Dr. K. London. Translated by E. S. Bensinger (*Review*), 215

Films: Another Dimension in (*Review*), 307; Educational, A National Encyclopædia of, and 16 mm. apparatus available in Great Britain, 1936. Edited by W. L. Lally (*Review*), 696

Finnish Entomological Society, Dr. W. Horn nominated an honorary corresponding member of the, 667
Fire Blight of Apples and Pears, Dr. K. G. Parker, 636
Fireflies in Jamaica, Flashing of, J. B. Buck, 801
Fire: Precautions in Electrical Stations, F. C. Winfield, 621; -Walking: Scientific Tests, 660; H. Price, 928
Fires in London [1837], 895
Fisheries Research, International, 337
Fishes: A History of, J. R. Norman, Second edition (*Review*), 654; Fresh-water, Visual Purple System in, Dr. G. Wald, 1017
Fishing Gear of England and Wales, An account of the. Third edition, 1049
Flame Gases, Height of the Combustion Levels attained in, Factors influencing the, Prof. W. T. David, 289
Flammarion's Annuaire Astronomique, 1937, 406
Flight, Human, Natural Limits of, H. E. Wimperis, 874
Flooding: in Southern England, 186; in East Anglia, 539
Floods: The, in the U.S.A., 185, 227; 277; in France and Southern England, 278; in the United States, The recent, Dr. C. E. P. Brooks, 400
Flora, Our Changing, Dr. R. W. Butcher, 1120
Florida, South, Suggested Botanic Garden in, 956
Flotation, Separation of Substances by, F. K. T. van Iterson, 687
Flower, Interpretation of the, Dr. Agnes Arber, 1115
Flowering Plants of the British Isles, Endemic, Wilmott, 292
Fluorene Compounds, Synthesis of, Prof. L. Mascarelli and others, 596
Flute, Physiology of Playing the, Dr. J. Roos, 74
Foam, Adsorption on, Dr. F. Schütz, 629
Fog-, Cloud- and Rain-Droplets, Microscopic Examination of, N. Fuchs and I. Petrjanoff, 111
Food: Conservation of, Science and the, T. Macara, 707; Supply, The National, 815; The Preservation of (*Review*), 946; Production, Modern, Applications of Chemistry to, Sir John Russell (Bedson lecture), 974
Foods and Drugs, Analytical Control of, 364
Foot-and-Mouth Disease Research Committee, Fifth Progress Report of the, 1033
Forbes's (J. D.): work on Terrestrial Magnetism [1837], 39; and von Buch [1837], 1029
Force Constants: and Structure, J. W. Linnett and Dr. H. W. Thompson, 509; and Molecular Structures, C. R. Bailey and J. B. Hale, 1112
Forest: Products Research Board, Report for 1935, 22; Insects, Prof. R. W. Doane, Prof. E. C. Van Dyke, Prof. W. J. Chamberlin and H. E. Burke (*Review*), 822
Forestry: Research in the Malay Peninsula, 295; in the Gold Coast, R. C. Marshall, 683; Herbarium, late Prof. A. H. Henry's, 920; Instructional Tours for Students of, Prof. R. S. Troup, 929
Forthcoming Books of Science, 464
Fossil: Man, Duration of Life in, H. V. Vallois, 208; Algæ in Boghead Deposits, Dr. K. B. Blackburn and Dr. B. N. Temperley, 340; Pollen in Scottish Jurassic Coal, Dr. J. B. Simpson, 673; a puzzling, D. J. Scourfield, 1023; Antelopes and Oxen of the Siwalik Hills, G. E. Pilgrim, 1023
Fossils in their original environment, Dr. H. Dighton Thomas, 1121
Fossilen Meeresboden, Die bionomische Einteilung der, H. Schmidt (*Review*), 902
Foveal Light Adaptation Process, W. D. Wright, 259
Fowl-Pox and its Transmission, R. L. Kaura and S. G. Iyer; A. L. Brody, 889
France: a Handbook for Beginners in French, Dr. Cloudesley Brereton, 103
Franklin Institute, Cancer Research at the, 543
French: Birth-Rate, Fall in, 146; Society of Clinical Biology, Prof. L. van Itallie awarded the Pasteur medal of the, 442; Air Ministry, Formation of a Committee on the requirements of the Air Force, 624; Academy of Medicine, award of the Albert I of Monaco prize to Drs. P. Bouin and Ancel, 835; League against the Venereal Peril, Prof. Levaditi nominated scientific director of the, 835
Freshwater Biological Association of the British Empire' Dr. E. B. Worthington appointed director of the Wray Castle Laboratory, 795
Fruit: Development, Inducement of, by Growth-promoting Chemicals, F. G. Gustafson, 209; Growing: Hardy, Sir Frederick Keeble and A. N. Rawes (*Review*), 449; Principles and Practice of (*Review*), 449; -flies, Biological Races in, A. D. Pickett, 1073
Fuel: Economy, Locomotive, Dr. P. Lewis-Dale, 76; Research Board, Report for year ended 31st March, 1936, 517; Briquetting, R. A. Strong, E. Swartzman and E. J. Burroughs, 848; Research Station: Annual Visitation, 1078
Fuels, Combustion of, Anti-Knocks and Pro-Knocks in the, A. V. Belov and Prof. M. B. Neumann, 798
Fumigants under Reduced Pressure, Absorption of, Dr. A. B. P. Page and Dr. O. F. Lubatti, 553
Fungi: Study of (*Review*), 91; Dermatophyte, Dr. R. M. Shaw and Dr. J. W. Macgregor, 377
"Furukawa Magnetic Alloy", High Permeability, 75
Future, A Short History of the, J. Langdon-Davies (*Review*), 129

Galaxy, The, Dr. J. S. Plaskett, 76
Galvanism, Power of [1837], 769
Galvanomagnetic Method of measuring Small Displacements, S. Reisch, 603
Gamma: Ray Excitation by Fast Neutrons, H. Aoki, 372
Rays: excited by Capture of Neutrons, J. H. E. Griffiths and Dr. L. Szilard, 323; Action of, on Growing and on non-Proliferating Bacteria, D. E. Lea, R. B Haines and C. A. Coulson, 426
γ-Rays, Absorption of, measured by their photo-effect in Beryllium, J. Rotblat, 963
Garden Plants, Diseases of, 253
Gardenia Canker, W. Buddin and Miss E. Wakefield, 764
Gas: Impregnated Cable, A. W. Arman, 516; -Storage of Fruit, Refrigerated, Dr. F. Kidd and Dr. C. West, 636; Engineers, Institution of, Dr. W. T. K. Braunholtz appointed secretary of the, 835
Gaseous: Discharge Tubes, Energy Distributions in the Spectra of some, R. G. Giovanelli, 603; State, Equilibrium and Kinetics in the, and in Solution, Dr. G. A. Benford, Miss B. S. Khambata and Dr. A. Wassermann, 669
Gases: Molecular Heats of, Temperature Drop effect in relation to the Determination of the, Prof. H. S. Gregory and R. W. B. Stephens, 28; Disperse Systems in, Dust, Smoke and Fog (*Review*). 458; in Metals, Role of, A. Portevin, G. Chaudron and L. Moreau, 1030
Gaultheorioside (ethylprimeveroside), J. Rabaté, 300
Gem-Stones (*Review*), 450
Genes in Man, Dominance of, Dr. S. G. Levit, 233
Genetics: in Madrid, Prof. J. B. S. Haldane, 331; Seventh International Congress of, Prof. O. L. Mohr, 666
Geodesics Within Matter, Prof. J. L. Synge, 156
Geographical: Literature, Index of, 63; Association, Annual Conference, 162
Geography: Progressive Teaching in, 162; and Economic Theory, Sir Josiah Stamp, 163; 311; and European Society (*Review*), 390
Geological: Survey of Great Britain and Museum of Practical Geology, Prof. E. B. Bailey appointed director of the, 102; Society: awards of the, 148; of America, Prof. A. Holmes elected a foreign correspondent of the, 190; Time Scale, W. D. Urry, 334; Society of London, election of officers, 442; Museum, Recent acquisitions at the, 623; Society of London, Proceeds of the Daniel Pidgeon Fund awarded to Dr. G. F. Claringbull and F. W. Cope, 752; Museum, Exhibition of Opals at the, 793
Géologie stratigrafique, Prof. M. Gignoux. Deux. édition (*Review*), 902
Geology: of the Currywongaun-Doughruagh Area, Co. Galway, L. M. Ingold, 82; in School Courses of General Science, Claims of, Prof. A. E. Trueman, 251; Dr. B. H. Knight, 329

Geometrical: Design, A. R. Green, 164; Optics, New Method in, C. W. Oseen, 722
Geometry in Germany, Development of the teaching of, Prof. G. Wolff, 163
Geomorphologie der feuchten Tropen, Prof. K. Sapper (*Review*), 902
German: Rontgen Society, Prof. A. Busi, Prof. A. C. Christie, Dr. B. K. Kirklin and Dr. E. Lazeanu nominated as honorary members of the, 107; Academy of Natural Philosophers, award of the Cothenius medal to Prof. P. Uhlenhuth, 408; Institute of Psychological Research, Foundation of a, 582; Academy of Natural Sciences, Halle, Prof. A. Bessemans elected a member of the, 667; Scholars travelling abroad, Regulations for, 746; Refugees as Istanbul University, 747; Airship Disaster, 832
Germanochloroform, Electrolysis of, or Germanohydrochloric Acid, A. Tchakirian, 300
Germany: and the Nobel Prizes, 228; and Science: Yesterday and To-day, 666; Conditions in [1837], 685
Gesneriaceæ, Physiology of Germination in, J. Jurišić, 427
Gesture Language, Sir Richard Paget, Bt., 198
Glamorgan County History. Vol. 1: Natural History. Edited by Prof. W. M. Tattersall (*Review*), 307
Glasgow University: Dr. J. W. S. Blacklock appointed St. Mungo (Notman) professor of pathology at the Glasgow Royal Infirmary; gift for the Chemistry Institute from Imperial Chemical Industries, Ltd.; resignation of Prof. E. B. Bailey, 208; impending resignation of Prof. G. G. Henderson; Dr. J. B. Rennie appointed lecturer in the practice of medicine, 479; Prof. A. E. Trueman appointed professor of geology in, 578; Dr. G. L. Montgomery appointed Gardiner lecturer in the pathology of diseases of infancy and childhood; gift from Sir William Waters Butler, 643; Gift by Prof. G. G. Henderson; award of doctorates to J. Bell, J. D. Loudon and Anne H. McAllister; conferment of honorary doctorates on Prof. J. Boeke, J. M. Cowan, Prof. T. K. Monro, Sir Robert Muir, Sir Albert Seward and Prof. R. Stockman, 1122
Glass Bricks, Some tests of thermal constants of, E. Booth, 977
Glucolysis without Phosphorylation in the Chick Embryo, Dr. J. Needham and H. Lehmann, 368
Gmelins Handbuch der anorganischen Chemie. Achte Auflage. System-Nummer 4: Stickstoff. Lief. 2. System-Nummer 4: Stickstoff. Lief 3. System-Nummer 4: Stickstoff. Lief 4. System-Nummer 23: Ammonium. Lief. 1. System-Nummer 35: Aluminium. Teil A, Lief. 3. System-Nummer 35: Aluminium. Teil A, Lief. 4. System-Nummer 55: Uran und Isotope, mit einem Anhang über Transurane (*Review*), 48
Gods: Battlefield of the, aspects of Mexican History, Art and Exploration, P. Kelemen (*Review*), 1089
Goethe medal for art and science, award of the, to Prof. H. Gloël, 442; Prof. Max Wien and Prof. O. Seyffert, 1103
Goitre, Œtiology of, 33
Gold Coast, Forestry in the, R. C. Marshall, 683
Gold: Deuteride Bands, S. Imanishi, 591; in Horse-tails, B. Němec, J. Barbička and A. Oborský, 301
Gorky Institute of Experimental Medicine, Moscow, Organization of a pharmacological department, 322
Gottingen, University of: Centenary of the, 701; J. D. Lambert, 930; The Massachusetts Institute of Technology and, 959
Graphite Crystals, Abnormal Unidirectional Diamagnetism of, Temperature variation of the, Prof. K. S. Krishnan and N. Ganguli, 155
Grass Drying, A Year's Progress in, E. J. Roberts, 363
Grasshoppers, British, and their Allies: a Stimulus to their Study, Dr. M. Burr; Dr. B. P. Uvarov (*Review*), 456
Grasshopper's Egg, Studies of the, Eleanor H. Slifer, 932
Gravitation, The Constant of, Prof. E. A. Milne, 409
Great: Barrier Reef, Mysids and Euphausiids of the, Prof. W. M. Tattersall, 846; Britain, The Trend of Population in, 564
Greek Birds, A Glossary of, Prof. D'Arcy Wentworth Thompson. New edition (*Review*), 305
Greenland, Capt. Graah's Expedition to [1837], 1080
Green Laurels: the Lives and Achievements of the Great Naturalists, D. C. Peattie (*Review*), 691
Greenwich, Royal Observatory, Annual Visitation, 1026
Gregory, David, Isaac Newton and their Circle: Extracts from David Gregory's Memoranda, 1677–1708. Edited by W. G. Hiscock (*Review*), 903
Gresham College, University of Cambridge and [1837], 643
Grid System in Great Britain, Control of the, J. D. Peattie, 405
Growth-Ratio, Differential, Inheritance of a, Dr. E. Ashby and L. C. Luckwill, 71
Gypsies, Serbian, Religious Beliefs of, Dr. A. Petrović, 594

Hæmochromogens, Coupled oxidation of Ascorbic Acid and, Dr. R. Lemberg, B. Cortis-Jones and M. Norrie, 1016
Half-Caste, C. Dover (*Review*), 1087
Hair in Health and Disease, The, E. Lawrence (*Review*), 737
Halle University, Dr. O. Gesner nominated professor, and director of the Institute of Pharmacology in, 107
Halley Lectures, Five (*Review*), 266
Hall's, Samuel, Marine Surface Condenser [1837], 644
Halogenobenzenes in the Gaseous Phase: Bromination of, Influence of Temperature and Catalysts on the Substitution Type, Prof. J. P. Wibaut and M. van Loon, 151
Halogen: -substituted Acetic Acids, Catalytic Decomposition of, in Liquid Systems, J. B. Senderens, 384; -Argento-Benzoic Complex Compounds, C. Prévost and J. Wiemann, 771
Hammond Electric Organ, The, 1043
Hannah Dairy Research Institute, Annual Report, 665
Hansen, Emil Chr., gold medal and prize, award of the, to Prof. A. Quintanilha, 960
Harmolita, Chalcid Wasps of the genus, W. J. Phillips, 117
Harmonics in Valves, Electron Inertia as the cause of, W. E. Benham, 591
Harris, Snow, at the United Service Museum [1837], 1079
Hartley, Marcellus, gold medal, award of the, to Dr. H. S. Cumming, 408
Health, Ministry of, Seventeenth Annual Report of the, 21
Hearing: Psycho-physics of, M. Upton and A. H. Holway (1 and 2), 645; and Deafness, French Association for Researches on, election as president, of A. Lumière, 667; Aids, Use of, A. W. G. Ewing, L. R. Ewing and T. S. Littler, 1115
Heat: The Polarization of [1837], 207; and Heat Engines, Examples in, T. Peel. Second edition (*Review*), 489; Engines, S. H. Moorfield and H. H. Winstanley. Second edition (*Review*), 489
Heathcoat's Steam Plough [1837], 685
Heavy: Elements, Transmutation of the, Lord Rutherford, 540; Ammonium Chloride, The Low Temperature Transformation of, Prof. A. Smits and G. J. Muller, 804; Water, Electrolytic Separation of, An effect of Rectified Current from a Tunger Valve upon the, T. Asada and E. Honde, 885
Hebrideans, The New (*Review*), 568
Heidelberg: University of, and New Conceptions of Science, 98; A Correction, Dr. E. Wolf, 959
Helium: Liquid, Latent Heat of Evaporation of, Prof. J. Satterly; Dr. J. Newton Friend, 472; Chemical Detection of, formed in Beryllium by Gamma Rays, Prof. F. A. Paneth and Dr. E. Glückauf, 712
Helminthological Research in India, Dr. G. S. Thapar, 639
Helminthosporium and *Curvularia* associated with Root-Rot of Wheat and other Graminaceous Plants, Species of, H. J. Hynes, 603
Hemaphorrhea, reflex reject of Blood and Air by the Phymateid Acridians, P. P. Grassé, 208
Henderson's Star Observations at the Cape [1837], 644

Henslow's "Descriptive and Physiological Botany" [1837], 601
Heredity: *versus* Environment, Dr. D. Forsyth, 768; in Ventral and Dorsal Areas, Localization of the factors of, A. Pictet, 855
Hero: The: a Study in Tradition, Myth and Drama, Lord Raglan (*Review*), 532; reply to review of, Lord Raglan, 833
Hexlet: The, Dr. F. Morley, 72; The Bowl of Integers and the, Prof. F. Soddy, 77; The, Prof. F. Soddy 154; T. Gosset, 251; Prof. F. Soddy, 252
Himly, Karl (1772–1837), 520
Hindenburg, Destruction of the, 832
Hirosima Wave Geometry and Field Theory, 893
Histomonas meleagridis from the Liver Lesions of a Hen, Cultivation of, Dr. H. P. Bayon and Dr. Ann Bishop, 370
History: English, The Science of, Sir Cyril Fox (*Review*), 213; Humanistic, F. S. Marvin (*Review*), 308
Hochfrequenztechnik, Lehrbuch der, Dr. F. Vilbig (*Review*), 1087
von Hoff, Carl Ernst Adolf (1771–1837), 895
Hoffmann Shocks, Reality of, A. Dauvillier and A. Rogozinski, 300
Holmes, Sherlock, a Drug Addict ?, Was, 21
Homo: *modjokertensis*, Dr. E. Dubois, 291; *sapiens* L., Lunar Periodicity in, Dr. D. L. Gunn, Penelope M. Jenkin and Dr. A. L. Gunn, 841
Honey Research at Rothamsted; appointment of Dr. C. R. Marshall, 23
Hooker's Aneroid Barometer, 995
Hopi: Economics, Family and Clan in, E. Beaglehold, 763; Ceremonial Dances, Clowns in, A. M. Stephen, 888
Hordenine, New Synthesis of, Y. Raoul, 209
Hormonsforchung, Methodik der, Dr. C. Bomskov. Band 1 (*Review*), 570
Hornbills, Nesting of, R. E. Moreau, 763
Horticultural Science in France, G. Truffaut, 709
Human: Machine, Reactions of the, J. Y. Dent (*Review*), 51; Problems of Progressive Industry, 85; Welfare and Human Efficiency, W. H. Smyth, 106; Heredity Bureau of, 147; Mind: The Dawn of the, a Study of Palæolithic Man, Dr. R. R. Schmidt. Translated by Prof. R. A. S. Macalister (*Review*), 454; Foot: The, its Evolution, Physiology and Functional Disorders, Prof. D. J. Morton (*Review*), 696; Malaria Parasites, A Presumptive Culicine Host of the, Prof. K. B. Williamson and Mahomed Zain, 714
Hume Rothery, β, Phases, The Existence-Range of the, M. Hara, 195
Hummer og Hummerkultur, Dr. A. Dannevig, 35
Hungarian Society of Public Health, Fiftieth Anniversary of the, 408
Hybrid Vigour in Plants, Dr. E. Ashby, 852
Hydrazoates, Thermolysis of, Activation energy of the Photogenic Reactions accompanying the, R. Audubert, 939
Hydrocarbons, Gaseous: saturated, at Low Pressure, Thermal Conductivity of the, R. Delaplace, 166; A Method of Analysis of Saturated and Unsaturated, under very Low Pressures, R. Delaplace, 686
Hydrogen: Isotopes in Complex Cobaltammines, Interchange of, F. W. James, Dr. J. S. Anderson and Prof. H. V. A. Briscoe, 109; Ion Concentration, Dependence of the Polarographic Reaction of Proteins on, R. Brdička, 301; and Hydroxyl Bonds, Isotope effect in, Dr. J. M. Robertson and A. R. Ubbelohde, 504; Bridges, Synchronized Oscillations in, Dr. M. L. Huggins, 550; Permeability of Metals to, Dr. C. J. Smithells, 1113
Hydrography of the Atlantic Oceans, G. E. R. Deacon (*Review*), 1085
p-Hydroxy Propenyl Benzene (Anol), Œstrogenic activity of, Prof. E. C. Dodds and W. Lawson, 1068
Hydroxyl, Hydrogen and, Bonds, Isotope effect in, Dr. J. M. Robertson and A. R. Ubbelohde, 504
Hygiene: in Institutions of Higher Education, Instruction in, Dr. J. P. Rogers, 664; Grundlagen, Methoden und Ziele der, Prof. W. Kollath (*Review*), 696
Iban or Sea Dayak Fabrics and their Patterns, Dr. A. C. Haddon and Laura E. Start (*Review*), 530
Ice: ordinary, nature of, N. J. Seljakov, 1081; Age; in Detail, The (*Review*), 817; The Quaternary, W. B. Wright. Second edition (*Review*), 817; -Water Relationships, a method for determining, by measurements of Dielectric Constant changes, L. T Alexander and T. M. Shaw, 1109
Ichthyologists and Herpetologists, American Society of, Election of Officers and honorary foreign members, 1014
Igneous Rocks, Interpretative Petrology of the, Prof. H. L. Alling (*Review*), 460
Iguanodons in the Brussels Museum, 15
Immunity of Plants to Disease, Dr. E. J. Butler and others, 297
Imperial: Agricultural Research Institute, The, New Delhi, Dr. W. Burns, 431; Leopold Caroline German Academy, Halle, Prof. K. Reublen, Prof. A. Dietrich and Prof. H. Seger elected members of the, 442; Forestry Institute, Oxford, The, 731
Index Generalis 1937 (*Review*), 906
India: Radio Research in, Prof. S. K. Mitra, 62; Prof. M. N. Saha, 63; North-West Frontier of, Races on the, Dr. G. B. Morant, 74; Phytopathology in, Dr. B. B. Mundkur, 334; Archæology in, Rao Bahadur, K. N. Dikshit appointed director general of, 408; National Institute of Sciences of, Prof. M. N. Saha elected president of the, 437; National Institute of Sciences, election of officers, 442; Public Health investigation in, 582; Science and Politics in, a Contrast, 605; Southern Pasteur Institute of, Annual Report, 624; Earthquakes in, W. D. West, 639; Helminthological Research in, Dr. G. S. Thapar, 639; Relation of Animal Nutrition to Public Health in, Col. A. Olver, 640; Cultural Contrast and Government in, 662; Museums of, Report on the, S. F. Markham and H. Hargreaves, 916, 934; Earthquakes in, W. D. West, 1118
India's Climax Vegetation, H. G. Champion, 639
Indian: History and Geography, Ancient, Studies in, 243; Institute of Science, Bangalore, R. H. Beckett appointed registrar of the, 408; Science Congress Association: Hyderabad meeting, 638; Village—its Past, Present and Future, Rao Bahadur T. S. Venkatraman, 638; Physiology, Lt.-Col. S. L. Bhatia, 640; Institute of Science, resignation of Sir C. V. Raman; appointment of C. E. W. Jones as registrar, 1102
Industrial: Recruitment, Problems of, 63; Management, Books on, 441; Psychology, National Institute of, T. G. Rose appointed general director of the, 624; Workers, Health and Safety of, 857
Industry: Progressive, Human Problems of, 85; and Society, Science, 525
Infants, Growth Curve of, Dr. C. B. Davenport and W. Drager, 209
Influenza: An Epidemic of [1837], 81; Epidemic, 190; 242
Infra-red Bands in the 3μ Region, Some, Dr. J. J. Fox and Dr. A. E. Martin, 507
Inorganic Preparations: a Systematic Course of Experiments, A. King (*Review*), 352
Insect Drift over the North Sea, Prof. A. C. Hardy and P. S. Milne, 510
Insects: The Ancestry of, Dr. A. D. Imms, 399; The Biological Control of, with a Chapter on Weed Control, Prof. H. L. Sweetman (*Review*), 449; Origin of, Dr. W. T. Calman, 806
Instruments de Musique, Origine des, A. Schaeffner (*Review*), 905
Integers, The Bowl of, and the Hexlet, Prof. F. Soddy, 77
Intellectual Liberty", "For, Society, Bulletin of the, 188
Intensities, minimal discrimination of, Law for, W. J. Crozier and A. H. Holway (1), 645
Interchangeable Manufacture, Prof. J. W. Roe, 748
Interference by Reflection from a Concave Spherical Mirror, O. U. Vonwiller, 343
Inter-Imperial Co-operation in Scientific Research, 304

Interpolation and Allied Tables (*Review*), 461
Interstellar: Ionized Titanium, Forbidden Transition in the Spectrum of, Dr. T. Dunham, jun., 246; Space? Molecules in, Prof. M. N. Saha, 840; Radio Disturbances, Origin of, F. L. Whipple and J. L. Greenstein, 897
International: Congress of Genetics and the U.S.S.R., 142; Geological Congress, 1937, 143; Cancer Research, 255; Fisheries Research, 337; Equity Tribunal, An, 361; Peace, Promotion of, 483; Faculty of Sciences, presentation of the gold medal of the, to J. L. Baird, 641; Council of Scientific Unions, The, 697; Association for Testing Materials, London Congress, 765; Electrodeposition Conference, The First, 808; Council of Scientific Unions, Third General Assembly, 869; Prof. C. Fabry elected president, 870; Peace, Dr. Murray Butler, 1047; Congress for the History of Science, forthcoming, 1049
Intestine, Absorption from the, Prof. F. Verzár, assisted by Dr. E. J. McDougall (*Review*), 309
Iodine: Oxides, Organic and Inorganic Chemistry of, Prof. I. Masson, 150; Compounds, Exchange Reactions of, H. A. C. McKay, 283; Solutions, Diamagnetism of, C. Courty, 1030
Ion, Negative, Formation, F. L. Arnot, 378
Ionization Constants of Organic Acids, Correlation of, with Dipole Moments, J. F. J. Dippy, 581
Ionosphere: Abnormalities of the, and Bright Solar Eruptions, R. Bureau, 110; Reflection from the, R. N. Rai, 115; Ions and Isotopes, J. Kendall, 384; Regularities and Irregularities in the, Prof. E. V. Appleton (Bakerian lecture), 1076
Iraq, Earliest Monumental Remains in, Prof. E. A. Speiser, 580
Ireland, The Secret Languages of, Prof. R. A. S. Macalister (*Review*), 692
Iron: Primary Oxide Film on, H. R. Nelson, 30; Passive Examination of, by Electron Diffraction, I. Iitaka, S. Miyake and T. Iimori, 156; -Nickel Alloys of High Permeability, W. F. Randall, 335; Inks in Antiquity, the use of, The Lachish Letters and, A. Lewis, 470; and Steel Institute, award of Bessemer gold medals to Col. N. T. Belaiew and A. Meyer, 498
Irradiation of Plants with Neon Light, J. W. M. Roodenburg and G. Zecher, 725
Isaria, *Cordyceps* and, Fungi, T. Petch, 159
Isles of the Seven Seas, C. Ingram (*Review*), 310
ψ-Isocyanine Dyes, Absorption Bands in the Spectrum of, Scheibe, Kandler and Ecker, 378
Isotopes, Separation of, G. Champetier, 38
Istanbul University, German Refugees at the, 747
Italy, Birth-Rate in, 408

Jaffe's Reaction, Chemistry of, for Creatinine, A. Bolliger, 523
Japan: Early Man in, Prof. S. Tokunaga, 502; Mineralogie von, Beitrage zur, Begrundet von T. Wada. Neue Folge, 1, Herausgegeben von T. Ito (*Review*), 611; ; The Earthquake Research Institute of, Dr. C. Davison, 615
Japanese Institute for Science of Labour, Annual Report, 620
Java, Early Man in, Dr. P. V. van Stein Callenfels, 294
Johns Hopkins School of Hygiene and Public Health, Prof. L. J. Reed appointed dean of the, 921
Joints, Corrosion of, J. Cournot and M. Baudrand, 125
Jupiter, Colour Variation in, The Equatorial Belts of, A. Stanley Williams, 596

Kaiser Wilhelm Institute for Cerebral Investigations, Prof. H. Spatz appointed director of the, 1103
Kantian Scholarship, An advance in (*Review*), 818
Kant's Metaphysic of Experience: a Commentary on the First Half of the "Kritik der reinen Vernunft", Prof. H. J. Paton. 2 Vols. (*Review*), 818
Katalyse und Katalysatoren in Chemie und Biology, Uber, A. Mittasch; Prof. M. Polanyi (*Review*), 268
Katanga Skull, Dr. M. Young, 475
Keratin Molecule, Constitution of the, Dr. J. B. Speakman and F. Townend, 411
Keris and other Malay Weapons, G. B. Gardner. Second edition (*Review*), 51
Kew's Contribution to Empire Botany, 850
King's England: The, a New Domesday Book of 10,000 Towns and Villages: Enchanted Land, A. Mee; Kent, A. Mee; Warwickshire, edited by A. Mee; Lancashire, edited by A. Mee (*Review*), 217
Kings and Councillors: an Essay in the Comparative Anatomy of Human Society, A. M. Hocart (*Review*), 653
Kingship, Evolution of (*Review*), 653
Kingston Valves for Steamships [1837], 812
Kiss Precise", "The, C. C. Mason; T. Gosset, 62
Klimatologie, Handbuch der, Herausgegeben von W. Koppen und R. Geiger. In 5 Banden. Band 1, Teil B: Die klimatologischen Elemente und ihre Abhangigkeit von terrestrischen Einflussen, Pro-. V. Conrad; Band 1, Teil C: Das geographische Systeme der Klimate, Prof. A. Koppen; Band 1: Titel, Vorwort, Inhalt, alphabetisches Sachregister; Band 2, Teil J: The Climates of North America. Part 1: Mexico, United States, Alaska, Prof. De C. Ward and Prof. F. Brooks (*Review*), 820
Knowledge, Unified, The Service of, Prof. A. B. Dobrowolski, 935
Kontinente, Die Entwicklung der, und ihrer Lebewelt, Prof. T. Arldt. Zweite Auflage (*Review*), 902
Krakatau: The Flora of, Sir Arthur W. Hill, 135; 1883–1933, Dr. W. M. Docters van Leeuwen. A: Botany, 136
Kutchin Potlatch, Dr. C. Osgood, 594

Lachish Letters, The, and the use of Iron Inks in Antiquity, A. Lewis, 470
Lac Research, Indian, Mrs. Dorothy Norris, 678
Ladder, the Endless [1837], 1122
Lake: Titicaca, South America, The Percy Sladen Expedition to, Prof. J. Stanley Gardiner, 353; George Region, Physiography of the, with special reference to the Origin of Lake George, M. D. Garretty, 522
Lambeth Degrees, Dr. C. Wall, 441
Lamellibranchs, Production of Large Broods in certain, in relation to Weather Conditions, A. C. Stephen, 561
Lancashire and Cheshire Fauna Committee, Twenty-Second Report, 708
Landolt-Bornstein Physikalisch-chemische Tabellen. Funfte Auflage, Erganzungsband 3. Herausgegeben von Prof. W. A. Roth und Prof. K. Scheel. Teil 3, Halfte 1 and 2 (*Review*), 93
Landscape, Buildings and, Conservation of, 345
Lanthanum, Supraconductivity of, Dr. K. Mendelssohn and J. G. Daunt, 473
La Plata Museum, Dr. W. Horn nominated an honorary academician of the, 667
Latham, Dr. John (1740–1837), 207
Laue Radiograms, Striped Spots of, L. Chrobak and J Chojnacki, 687
Laue's Diagrams, Twenty-fifth Anniversary of, A. E. H. Tutton, 517
Lausanne University, conferment of honorary degrees on Sir Maurice Amos, Sir Frederick Gowland Hopkins, Prof. G. Barger and Prof. G. Rudler, 1050
Lawes Agricultural Trust Committee, resignation by Lord Clinton of chairmanship; Prof. H. E. Armstrong appointed chairman, 877
Layer-Line and Debye Photographs by means of the characteristic X-Rays of the Crystal itself, C. Finbak and Prof. O. Hassel, 194
Lead: Sheaths of Electric Cables, Dr. P. Dunsheath, 364; Extrusion Phenomenon, A, Dr. P. Drunsheath, 755; B. Jones, 1071
Leaf-roll in the Field, A Ten-Year Experiment on the spread of, Prof. P. A. Murphy, 480

League of Nations: and Nutrition, 403; Dr. F. G. Bourdreau appointed executive director of the Milbank Memorial Fund, 408; Health Section, Prof. G. Bastianelli nominated as president of the special committee for malaria, 710
'Leather Jackets', Lead Arsenate treatment of, R. B. Dawson and R. B. Ferro, 253
Leeches of the North Sea and Baltic, K. Herter, 253
Leeds University: Dr. J. B. Speakman appointed reader in textile chemistry and Dr. W. T. Astbury reader in textile physics; Prof. W. MacAdam elected professor of medicine, Prof. J. le F. C. Burrow professor of clinical medicine and Dr. S. J. Hartfall professor of therapeutics and applied pharmacology, 560; Annual Report; gift to F. Parkinson, 726
Legion of Honour: rank of Chevalier of the, awarded to Prof. J. B. S. Haldane, 190; conferment of rank of Commander on President J. B. Conant, 281; Prof. P. Rivet created a Commander of the, 442
Leicester, Roman, 404
Lemna minor, Growth of, E. J. Winter, 1070
Leopold Caroline German Academy of Natural Philosophy, Halle, Dr. D. Giordano, Prof. B. Peyer and Prof. Brouwer elected members of the, 148
L'Espèce humaine, Encyclopédie française. Tome 7 (*Review*), 4
Librarianship in relation to Scientific Research, 429
Lichens found in Ireland, Chemical Constituents of, J. Breen, G. M. Kennedy, J. Keane and T. J. Nolan, 521
Life, Tracing the Dawn of, further Backwards, late Dr. R. J. Tillyard (Cawthron lecture), 377
Light: White: Phenomena of Luminescence relating to the production of a sensibly, M. Servigne, 82; Production of, by means of a Single Luminescent Tube, G. Claude, 82; by the Electrical Luminescence of Gases, M. Laporte, 124; Neutrino theory of, Prof E. C. G. Stueckelberg, 198; N. S. Nagendra Nath, 331; Production of, by Bacteria, Influence of Salts on the, F. Bukatsch, 523; Absorption of, by Atoms and Molecules, Prof. S. Datta, 638; and Corpuscles, Intrinsic Properties of, from Distant Sources, F. Zwicky, 729; Penetration into the Sea of, of various Wave-lengths measured by Emission or Rectifier Photoelectric Cells, Dr. H. H. Poole and Dr. W. R. G. Atkins, 812; Neutrino theory of, A. Sokolow, 1071
Lightning: Combined Oscillographic and Camera studies of, Dr. B. F. J. Schonland, D. B. Hodges and H. Collens, 167; B. L. Goodlet, 201; 478; Discharge, Diameter of, Dr. B. F. J. Schonland, 722; Conductors for Ships [1837], 1079; Photograph, a curious, C. S. Ronayne, 1080; Progressive, D. J. Malan and H. Collens (3), 1123
Lilacs, H. G. Hillier, 159
Lily Year-Book, The R.H.S., 502
Linéaires hyperboliques, Méthode des caractéristiques pour l'intégration des équations aux dérivées partielles, Mlle. Hélène Freda (*Review*), 822
Linnean Society of London: election as foreign members of the, of Dr. R. Dohrn, Dr. H. A. Spoehr, Prof. E. A. Stensio, Prof. N. E. Svedelius and Dr. R. Woltereck, 915; presentation of the Linnean gold medal to Dr. F. F. Blackman and the Trail award to Dr. C. F. A. Pantin; election of officers, 915
Liquids: Semi-Crystalline Nature of, Prof. P. Debye, 255; Structure of, 272; Acoustic Spectrum of, Sir C. V. Raman and B. V. Raghavendra Rao, 584
Lithium: Nitrate, Thermal Dissociation of, M. Centnerszwer and M. Blumenthal, 167; in Sea-Water, Determination of, J. Bardet, A. Tchakirian and Mlle. Raymonde Lagrange, 480
Liverpool: Geological Society, award of the medal of the, to Dr. E. Neaverson, 281; University, conferment of honorary doctorates on Lord Leverhulme, Sir Hector Hetherington, Prof. C. T. R. Wilson, A. P. M. Fleming and R. Dussaud, 1122
Lobster Research in Norway, 35
Local History, Writing of, L. F. Salzman, 1120
Lochaber Water Power Scheme, A. H. Naylor; Dr. B. Cunningham, 295
Lockyer, Norman, Observatory, D. L. Edwards appointed director and D. R. Barber assistant, 107
Locomotive: Furnace Control, V. Binns and S. Bairstow, 119; Boilers, Heat Transfer in [1837], 258
Locustana pardalina, Wing abnormality in, Prof. T. F. Dreyer, 197
Locusts: in Malaya, G. H. Corbett and N. C. E. Miller, 847; Respiration in, Dr. A. G. Hamilton, 1114
Logarithmetica Britannica: being a Standard Table of Logarithms to Twenty Decimal Places, Dr. A. J. Thompson. Part 7 (*Review*), 461
Logging-Transportation: the Principles and Methods of Log Transportation in the United States and Canada, Prof. N. C. Brown (*Review*), 654
Lombroso, Cesare, prize for criminal anthropology, Award of the, to Dr. L. Vervaeck, 243
London: Hospital, Researches from the Wards and Laboratories of the, 1936, 667; School of Economics and Political Science, Prof. A. M. Carr-Saunders appointed director of the, 896; 915; University: Benefaction by H. Price; Dr. F. E. Zeuner appointed honorary lecturer in geochronology at the Institute of Archæology, 166; Complimentary dinner to H. Price for his work, and generosity to, 187; conferment of title of professor on V. C. Illing and Dr. W. H. Newton and that of emeritus professor on Sir T. Percy Nunn, 208; conferment of title of professor on Dr. A. C. Chibnall and that of emeritus professor on Prof. E. G. Cullis; Dr. F. G. Gregory appointed professor of plant physiology at the Imperial College—Royal College of Science; Prof. F. A. P. Aveling, Miss Agnes S. Paul, Col. G. S. Szlumper and S. J. Worsley appointed fellows of King's College; Prof. R. Pearl appointed Heath Clark lecturer for 1937, 382; Dr. H. L. Eason appointed principal, 539, 560; Prof. S. Sugden appointed professor of chemistry at University College; conferment of title of reader in mining geology on Dr. W. R. Jones and that of reader in palæontology on Dr. W. F. Whittard; donations of the late Mrs. Mary Woodgate Wharrie to the Institute of Archæology, 560; Institute of Archæology, 791; J. Kirk appointed S. A. Courtauld professor of anatomy at the Middlesex Hospital Medical School; conferment of title of professor on Dr. W. D. Newcomb; award of the Petrie medal to Prof. J. D. Beazley; award of Dunn exhibitions to J. W. Paulley and P. Harvey, 938; University, Student enrolment of, 975; naming of two halls as, respectively, the "Macmillan Hall" and the "William Beveridge Hall," 1079
Long Ashton Research Station, 874
Long-chain Compounds of the Paraffin type, Dr. A. Muller, 255
Longitudes and Azimuths, Astronomical determination of, Prof. N E. Norlund (George Darwin lecture), 894
Lophyophyllum cyathophylliodes Vaughan, L. B. Smyth, 426
Low Temperature: Thermometry, Prof. Keesom, 293; Carbonization Plant, 749
Luminous Efficiency of Rays entering the Eye Pupil at different points, Dr. W. S. Stiles and B. H. Crawford, 246
Lyell: and his views on Geology [1837], 425; and his "Principles" [1837], 769
Lyotropic Series and Free Energies, A relation between the, Dr. L. H. N. Cooper, 284

McCormick and the Reaping Machine, Prof. J. Hendrick, 197
Macculloch's Geological Map of Scotland, V. A. Eyles, 974
McGill University, gift from the Rockefeller Foundation, 243
Macnish, Robert (1802–37), 123
Madrid, Astronomical Observatory, Annual for 1937, 624

Magic Squares: of $(2n+1)^2$ Cells, M.-J. van Driel (*Review*), 134; Easy Methods for the Construction of, Major J. C. Burnett; J. A. Todd (*Review*), 394
Magmatic Stoping in a Dyke at Hartley, N.S.W., A. G. Culey and G. A. Joplin, 522
Magnesia, Influence of, on the working of a carbide furnace, C. Aall, 1081
Magnesium Alloys for Aircraft, Dr. C. H. Desch, 144
Magnetic: Effects associated with Bright Solar Eruptions and Radio Fade-outs, A. G. McNish, 244; and Electrical Dimensions, Sir James Henderson; Prof. G. W. O. Howe, 473; Sir James Henderson, 676; Prof. W. Cramp, 677; Disturbances and Auroras, 790; Rev. J. P. Rowland, 835; and Electrical Dimensions, Prof. G. W. O. Howe; Prof. C. L. Fortescue, 844
Magnetochemie, Prof. W. Klemm (*Review*), 489
Magneto-optik (ohne Zeeman-Effekt), Prof. W. Schutz (Review), 51
Maiden Castle, Dorchester, Dr. Mortimer Wheeler, 424
Maidenhair Tree and its Allies, The Geological History of the, Sir Albert Seward, 741
Maize, Mutation Rate in Somatic Cells of, D. F. Jones, 209
Malaria: in Soviet Russia, Decline in, Prof. Sergiyev, 22; Parasites, New Knowledge of the Life-Cycle of, Lt.-Col. S. P. James and Dr. P. Tate, 545; in Europe: an Ecological Study, Dr. L. W. Hackett (*Review*), 860
Malay: Peninsula: Aboriginal Tribes of the, H. D. Noone, 241; ; Forestry Research in the, 295; Magic, J. Cuisinier, 514
Mammalian: Kidney, Structural Laws of the, with a Theoretical derivation, Prof. E. J. Conway, 250; Gonad, Development *in vitro* of the, P. N. Martinovitch, 413
Mammals: The Eggs of, Prof. G. Pincus (*Review*), 455; Ova of, Changes in the [1837], 727
Mammary Growth, Diphenyl Compounds and, Dr. G. A. Grant, 155
Man: Changing, the Education System of the U.S.S.R., Beatrice King (*Review*), 462; Early, Distribution and Characteristics of, 723
Manchester University: grant from the Rockefeller Foundation; resignation of R. W. James and Dr. D. Sheehan; Dr. S. Tolansky appointed lecturer in physics, W. S. Walker and W. G. Wainwright demonstrators in chemical technology and H. B. May assistant lecturer in bacteriology, 811; resignation of Prof. W. L. Bragg, 854; *Journal* of, No. 1, 1102; grant from the Rockefeller Foundation; institution of a chair of theoretical Physics and appointment of Prof. D. R. Hartree; Dr. J. G. Woolham appointed honorary assistant lecturer in Physiology; resignation of Dr. J. M. Jackson and Dr. F. A. Todd, 1122
Mandelic Acid in Urinary Infections, 160
Manganese Hydride, MnH, Band Spectrum of, Dr. R. W. B. Pearse and A. G. Gaydon, 590
Mankind, The Study of, Prof. R Ruggles Gates (*Review*), 4
Manures and Manuring, 582
Maps: The World in, a Study in Map Evolution, Prof. W. W. Jervis (*Review*), 608; Through the Ages, E. Heawood (*Review*), 608
Marine: Corrosion of Extra-mild Steel, Action of various additions in Small Proportions on the, A. Portevin and E. Herzog, 166; Screw Propulsion, Centenary of Practical, 279; Cold-blooded Animals, Rate of Tissue Metabolism of, in Different Latitudes, Prof. H. Munro Fox and C. A. Wingfield, 369; Radio Progress: a Survey of, with special reference to R.M.S. *Queen Mary*, Commdr. F. G. Loring, W. L. McPherson and W. H. McAllister, 622; Organisms, The Plunger Jar for Rearing, D. P. Wilson, 623; Zoo-geography (*Review*), 694; Invertebrates, Spectrographic analysis of, with special reference to the chemical composition of their environment, D. A. Webb, 1080
Markets and Men: a Study of Artificial Control Schemes in some Primary Industries, J. W. F. Rowe (*Review*), 459
Marmite, Medicinal uses of, 379
Marriage Conditions in a Palestinian Village, Dr. Hilma Granquist. 2 Vols. (*Review*), 49
Massachusetts Institute of Technology, Bequest to, by C. Hayden; Dr. K. T. Compton, 279
Mass-Spectrograph, A New, Dr. J. Mattauch, 420
Materials: Strength of, Dr. N. P. Inglis, 119; and their Testing, Joint Committee on, 707
Mathematical: Association, Annual Meeting; Prof. L. N. G. Filon elected president, 163; Functions, Higher, Tables of the, computed and compiled under the direction of H. T. Davis. Vol. 2 (*Review*), 461 Snack Bar: a Collection of Notes and Results, N. Alliston (*Review*), 461
Mathematics: Applied, in School Training, Prof. A. R. Forsyth, 163; History of, in Schools and Universities, R. M. Gabriel, 164; Elementary, An Illustrated Historical Time Chart of, E. J. Edwards. In 5 sections (*Review*), 460; Practical, Studies in (1), A. C. Aitken, 561
Mating, Effect of Testosterone Propionate on, Dr. H. A. Shapiro, 588
Maturity, Early, Instances of [1837], 81
Maya Indians, Food of the, Dr. F. G. Benedict and Dr. M. Steggerda, 970
Meccanica atomica, Fondamenti della, Dr. E. Persico (*Review*), 394
Mechanized Farming, Conference on, 164
Medical: Literature in 1836, 165; Science in Tropical Countries, Application of, Prof. E. Mellanby (*Review*), 732; Research: Council, Report of the, for the year 1935–1936, 825; in 1936, 825; Profession, English [1837], 853; Officer of Health in Present-day Germany, The (*Review*), 862, Education in the United Kingdom, General Council of, Sir Arthur MacNalty nominated a member of the, 1103
Medicine: A Hundred Years of, Prof. W. E. B. Lloyd (*Review*), 129; European, in the East [1837], 559; in Italy [1837], 727
Medieval Cleric, The Mind of a (*Review*), 131
Meghalaya (Garo-Khasi-Jaintia), Le plateau de, Dr. S. P. Chatterjee (*Review*), 489
Mellon Institute of Industrial Research, Dr. L. W. Bass appointed assistant director of the, 107; 849
Membranes: Semipermeable, New Method of Preparing, A. Grumbach and P. Vidal, 384; Natural and Artificial, Prof. E. K. Rideal, 988
Meosophyll in the Leaf, Wettability of the cellulose walls of the, Prof. D. H. Bangham and Prof. F. J. Lewis, 1107
Mercurialis perennis, Precise Distribution of, according to Soil Hydrogen Ion Concentration, J. F. Hope Simpson, 632
Mercury: Vapour Arcs, Enlargement of the Green line (5461 A. Hg) in, under High Pressure, L. Grillet, 480; Chloride (HgCl), Spectrum of, and Samuel's Theory of Linkage, Dr. K. Wieland, 590; Poisoning, Acute, in a Respiration Chamber, H. Christensen, M. Krogh and M. Nielsen, 626; Vapour, Magnetic Susceptibility of, J. S. Shur, 804; Discharge Lamps, New, J. N. Aldington and G. O. Stephens, 971; Arcs, Prof. F. J. Teago and J. F. Gill (*Review*), 985
Merseyside Fauna and Flora, 242
Messel Research Fellowship, award of a, to Dr. J. E. Harris, 19
Metal: -Ammonia Ions, A Possible Acid-Dissociation, and its Bearing on Certain Reactions, F. J. Jarrick, 507; Dr. J. S. Anderson, N. L. Spoor, and Prof. H. V. A. Briscoe, 508; Surfaces, Polished, Structure of, S. Dobinski, 764; Spraying, E. C. Rollason, 807
Metallic: State, Modern Theory of the, Prof. A. Sommerfeld, 255; Deposits, Application of Electrolytic Polishing to the Study of, P. Jacquet, 342; Ions: on Films at Interfaces and on the Surface of Water, Effects of Traces of, Dr. R J. Myers and Prof. W. D. Harkins, 367; on Monolayers, Effects of Traces of, Dr. J. S. Mitchell, Prof. E. K. Rideal, and Dr. J. H. Schulman, 625; Dr. Conmar Robinson, 626; Films: Thin, Structure of, at Low Temperatures, H. Hass,

807; The So-called 'Transition Temperature' of, T. Fukuroi, 884; Solutions, Quantitative Analysis of, by Means of the Spectrograph, P. Jolibois and R. Bossuet, 939
Metallurgical Abstracts (General and Non-Ferrous). Edited by G. Shaw Scott. Vol. 2 (New Series) (*Review*), 462
Metals: Institute of, Dr. H. Moore and W. Murray Morrison elected fellows of the, 322; and Alloys, The Theory of the Properties of, Prof. N. F. Mott and Dr. H. Jones (*Review*), 348; Institute of, Developments of the, 438; and Alloys, Corrosion Resistance of, R. J. McKay and R. Worthington (*Review*), 462; Institute of, Journal of the, Edited by G. Shaw Scott. Vol. 58 (*Review*), 462; Strain Energy in, Absorption of, N. A. de Bruyne, 633; Optical Constants of, A Photo-Electric Method for the Measurement of the, J. Bor, 716; Flow of, Prof. E. N. da C. Andrade, 793; Research in, Institute for, Sendai, 1049; Permeability of, to Hydrogen, Dr. C. J. Smithells, 1113
Metamorphosis, Periplutonic and Enorgenic Regional, F. E. Suess, 428
Metazoa, Digestion in, Prof. C. M. Yonge, 554
Meteor: Streams, R. A. McIntosh; Dr. M. Davidson, 293; Heights from the Arizona Expedition, E. Öpik, 807
Meteorite, Rusting of a, 540
Meteorites and the Craters on the Moon: Dr. L. J. Spencer, 655; W. H. Steavenson, 968
Meteorological Chronology, A, C. E. Britton, 996
Meteors, Characteristic Curves for, J. G. Porter, 1024
Metopa Grœnlandica in a Lamellibranch, K. Stephensen and G. Thorson, 333
Mexico, Historic Flora of, 256
Michelson-Morley Experiment, A Simple Means of Checking the, Prof. W. B. Cartmel, 110; 243
Microphthalmia and Other Eye-Defects throughout Fourteen Generations of Albino Rats, A. M. Hain, 40
Micro: -Gap Switch, The, Prof. W. M. Thornton, 160; and Macro-Analysis (*Review*), 392; -Chemical Club, election of officers, 503
Microscope: The, Prof. S. H. Gage. Sixteenth edition (*Review*), 455; Fittings, Standardization of, 665
Midwives Board, Central, Annual Report for Year Ended March 31, 1936, 581
Migmatites of Central Sweden, N. H. Magnusson, 420
Milk-Drinking Habits of School Children, 419
Mineralogie: Prof. R. Brauns (*Review*), 133; Lehrbuch der, Prof. W. Schmidt und Dr. E. Baier (*Review*), 570
Mineralogy: An Introduction to the Study of Minerals and Crystals, Prof. E. H. Kraus, Prof. W. F. Hunt, and Prof. L. S. Ramsdell. Third edition (*Review*), 133; Elementary (*Review*), 133
Minerals: in France, Production of, [1837], 123; Getting Acquainted with, G. L. English (*Review*), 460; Rock-Forming, Hydrolysis of, Dr. A. Brammall and J. G. C. Leech, 754
Mines: A National School of, [1837], 559; Ventilation of, [1837], 937
Minnesota, Early Man in, Prof. A. E. Jenks, 365
Minnow, Black-Headed, Spawning of, L. R. Richardson, 419
Miocene Implements in the Ipswich Museum, 994
Mite, Littoral, Biology of a, H. Madsen, 715
Mitochondria in Plant Cells, Presentation of a Film on the, A. Guilliermond, F. Obaton, and R. Gautheret, 480
Mnemiopsis leidyi Agassiz, Regeneration of Plate Rows in, B. R. Coonfield, 897
Mohammedan Marriage Customs, Prof. E. Westermarck (*Review*), 49
Molard, Claude-Pierre (1758–1837), 298
Mole Crickets and their Allies, F. Carpentier, 932
Molecular Structures, Force Constants and, C. R. Bailey and J. B. Hale, 1112
Molecules: Large, Synthesis of, Prof. H. Mark, 749; in Interstellar Space? Prof. M. N. Saha, 840
Molluscs, Four, Rarely Recorded from the Red Sea, Dr. C. Crossland, 31
Molybdenum, Distortion and Yield Point of, P. Túry and S. Krausz, 30
Monodeuteroethylene, Roman Spectrum of, J. M. Delfosse, J. C. Jungers, G. Lemaitre, Y. L. Tchang and Prof. C. Manneback, 1111
Monolayers, Effects of Traces of Metallic Ions on, Dr. J. S. Mitchell, Prof. E. K. Rideal, and Dr. J. H. Schulman, 625; Dr. Conmar Robinson, 626
Montserrat and the West Indian Volcanoes, Sir Gerald P. Lenox-Conyngham, 499; 907
Monuments of Antiquity, Preservation of, 875
Moon: Earth and, Figures of, Dr. H. Jeffreys, 471; Craters on the, Meteorites and the, Dr. L. J. Spencer, 655; W. H. Steavenson, 968; Motion and Figure of the, Dr. H. Spencer Jones, 971
Moscow, New Central Botanical Gardens for, 995
Moth, Life in a, Expectation of, Prof. R. Pearl and J. R. Miner, 678
Motor-Car Inspection, Need for, 664
Motors, Electrical, Control of, P. B. Harwood (*Review*), 985
Mount Athos, A Visit to, [1837], 81
Mule Deer of the Pacific Region of America, I. M'T. Cowan, 475
Muscle Hæmoglobin *in vitro*: Experiments on, The Instantaneous Measurement of Muscle Metabolism, G. A. Millikan, 812
Museum Exhibits *de luxe*, Prof. A. A. Allen, 22
Museums: National, of Natural History, 34; and Type Specimens, Dr. R. Broom, 62; Dr. W. D. Lang, 191; of India, Report on the, S. F. Markham and H. Hargreaves, 916; 934
Mushroom, Spores of the, Miss D. M. Cayley, 117
Music in Films (*Review*), 215
Musical Instruments and their Distribution, Dr. A. C. Haddon (*Review*), 905
Mycology, A Text-Book of, Prof. E. A. Bessey (*Review*), 91

N_2+, Dissociation of, Dr. R. K. Asundi and Prof. R. Samuel, 375
Nanga Parbat, disaster of the German expedition to, 1099
Narcissus, White Mould Disease of the, Dr. P. H. Gregory, 806
Native: Races and Nationalism in Africa, 169; Policy in the Empire, 1083
National: Hospital for Nervous Diseases, Dr. J. Doupe appointed a senior fellow in the Neurological Research Unit, 65; Industrial Health Service, A, 280; Government, The Case for the, Earl de la Warr, 578; Trust, gift to the, 583; Research Laboratories, Ottawa, work of the, 620; Well-being, Physical Training and, 647; Radium Trust and Radium Commission, 1935–36, Seventh Annual Reports of the, 699; Maritime Museum, 748; Physical Laboratory: Prof. W. L. Bragg appointed director of the, 830; Annual Report for 1936, 996; Board of Health [1837], 1029; Trust, Powers of the, 1099; Agricultural Research Bureau, Shaolingwei, Nanking, Dr. H. L. Richardson appointed adviser in soils and fertilizers to the, 1102
Nationalism and Land Utilization in Britain, Dr. D. Stamp, 441
Natural: History: National Museums of, 43; A New (*Review*), 175; Edited by Dr. C. Tate Regan (*Review*), 175; of Glamorgan (*Review*), 307; Colour Eclipse Photography, Dr. I. C. Gardner, 434; History Exhibition at Wye, 500; History, Personalities in (*Review*), 691
Nature: in Britain: An Illustrated Survey, Introduced by H. Williamson (*Review*), 455; Laws of, on the origin of, Prof. E. A. Milne, 997; Competition and Co-operation in, Prof. F. E. Weiss, 1120
Nauplii, Reactions to, of Light, S. Ishida, 419
Naven: A Survey of the Problems Suggested by a Composite Picture of the Culture of a New Guinea Tribe Drawn from three Points of View, G. Bateson (*Review*), 454

Nebulæ, Distribution of, Effects of Red Shifts on the, Dr. E. Hubble, 209
Nematology, An Introduction to, B. G. Chitwood and M. B. Chitwood. Section 1, Part 1 (*Review*), 654
Nemertea of the John Murray Expedition, J. F. G. Wheeler, 888
Nemertine, A New, Prof. W. J. Dakin and M. G. C. Fordham, 74
Neon: Light, Irradiation of Plants with, J. W. M. Roodenburg and G. Zecher, 725; Radioactive, Dr. T. Bjerge, 757
Nerve, from Amphioxus to Man (*Review*), 650
Nervous System of Vertebrates, Including Man, The Comparative Anatomy of the, Prof. C. U. A. Kappers, Prof. G. C. Huber, and Prof. Elizabeth Caroline Crosby. 2 Vols (*Review*), 650
Neuro-embryology: An Experimental Study, Prof. S. R. Detwiler (*Review*), 532
Neuroptera, Chromosome Behaviour and Phylogeny in the, H. Klingstedt, 468
Neutrino Theory: of Light, Prof. E. C. G. Stueckelberg, 198; N. S. Nagendra Nath, 331, Relations in β-Ray Transformations and the, Dr. H. O. W. Richardson, 505; A. Sokolow, 1071
Neutron, Disintegration of the, An Attempt to Detect the, C. W. Gilbert, C. L. Smith, and J. H. Fremlin, 796
Neutrons: in Silver Nuclei, Resonance Levels of, C. Y. Chao and C. Y. Fu, 325; Free, A Method of Measuring the Magnetic Moment of, Dr. O. R. Frisch, Dr. H. von Halban, jun., and J. Koch, 756; C-, Temperature Equilibrium of, Dr. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 922; Free, Sign of the Magnetic Moment of, Prof. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 1021; fast, Artificial Radioactivity produced by, and their inelastic collisions, J. Rotblat, 1110
New: Commonwealth Society and Institute, Fourth Annual Report, 708; Delhi, The Imperial Agricultural Research Institute, Dr. W. Burns, 431; Forest, The, 597; Guinea, Art and Life in, Dr. R. Firth (*Review*), 389; South Wales, Oceanography in, Prof. W. J. Dakin and A. N. Colefax, 580; Year Honours, 225; York: Academy of Sciences, election as honorary members of Prof. K. S. Lashley, Prof. H. Breuil, Dr. J. S. Huxley, Dr. A. Hrdlička, Dr. A. C. Haddon, Sir Arthur Hill, Prof. M. Caullery, and Prof. O. Duboscq, 190; Sir Albert Seward elected an honorary member of the, 281; Laboratory of Industrial Hygiene, Incorporation of the, 544; Zealand: Scientific Research in, 403; Earthquakes in, Dr. J. Henderson and R. C. Hayes, 420; Natural History Collection from, [1837], 685; Discharged Soldier Settlers in, 751; Handbook, 876; York, Anti-Noise Campaign in, 1063
Next Hundred Years: The, The Unfinished Business of Science, Prof. C. C. Furnas (*Review*), 129
Nickel Wire, Abnormally High Magnetic Permeability of, Obtained by Surface Treatment, Dr. T. F. Wall, 928
Nicotinic Acid and the Growth of *Staph. aureus*, B. C. J. G. Knight, 628
Nigeria and the Sahara, Dr. J. D. Falconer, 199
Night Sky: in February, 190; in March, 365; in April, 544; in May, 752; in June, 920; in July, 1103; Colour of the, Photo-Electric Study of the, R. Grandmontagne, 427
Nile: The, The Life-Story of a River; from the Source to Egypt. E. Ludwig, translated by Mary H. Lindsay; Dr. H. E. Hurst (*Review*), 351; Dry Crossings of the, E. J. Wayland; Dr. H. E. Hurst, 961: Dr. A. E. H. Tutton, 994.
Nitric Oxide: Reaction of, with Hæmoglobin and Methæmoglobin, Prof. D. Keilin and E. F. Hartree, 548; Inhibitions of Organic Decompositions by, Dr. H. W. Thompson and M. Meissner, 1018
Nitrides (Hydrozoates), Emission of Ultra-Violet Radiation in the Course of the Slow Decomposition of, R. Audubert and H. Muraour, 480
Nitrogen: Active, Prof. J. Kaplan, 115; Absorption, Influence of Elements Added to Steel on the, on Fusion in the Arc, A. Portevin and D. Séferian, 208; -Mercury Systems Excited by α-Rays, Action of Iron Oxide on the Emission Spectrum of, A. Luyckx, 672; Transformations in the Soil, Prof. N. R. Dhar, 894
Nobel Prizes, Germany and the, 228
Nobility, Shield of, Prof. W. Koppen awarded the, by the German Chancellor, 1014
Noise: Campaign in Russia against, 64; on the Road, 893
Non-Manual Workers, Statistics Concerning, 542
North: Africa: Prehistory of, Chronological Problems in the, R. Vaufrey, 432; Prehistoric Cultures and Chronology in, R. Vaufrey, 438; American Continent, Surface of the, [1837], 521; -East Land: Oxford University Expedition to, 1935–36, Biological Work of the, D. B. Keith, 55; Radio and Magnetic Observations at, During the Total Solar Eclipse of June 19, 1936. A. B. Whatman and R. A. Hamilton, 69; Pole, Soviet expedition to the, 955; 990
Norway, Regulation in, against Use of Alcohol by Professional Motor-Drivers, 281
Nottingham, Local Archæological Studies in, 994
Nova Lacertæ, 1936, Light Variations of, H. Grouiller, 771
Nubia, Archæological Expedition to, Sir Robert Mond, 103
Nucleic Compounds of Plants, Alteration of the, in the Course of their Extraction in a Trichloracetic Medium, E. Michel-Durand, 602
Nucleus, Enchromocentre Type of, and Feulgen's Stain, G. Yamaha and S. Suematsu, 889
Nuculid Bivalves of the Genus *Acila*, Dr. H. G. Schenck, 319
Number 137 Again, Mysterious, L. Infeld, 679
Numbers, randomly arranged set of, some distributions associated with a, W. O. Kermack and A. G. M'Kendrick, 976
Nutrition, Advisory Committee on, First Report, 815

Oak-Galls in Theophrastus, Prof. G. Senn, 684
Observatory, Jubilee number of the. 1013
Oceanic Basins and Continental Masses, Permanence of, Sir Thomas Holland (Huxley memorial lecture), 809
Oceanography in New South Wales, Prof. W. J. Dakin and A. N. Colefax, 580
Odours, Therapeutic Use of, [1837], 341
Œnothera, Non-Disjunction and Trisomics in, C. E. Ford, 159
Œstrin Threshold, Cyclical Fluctuations in, Dr. S. Zuckerman, 628
Œstrogenic Agent, A Simple Aromatic with an Activity of the Same Order as that of Œstrone, Prof. E. C. Dodds and W. Lawson, 627
Oil Engine, Practical Development of the, J. W. Young, 579
Oken, Lorenz, und Georg Buchner, J. Strohl (*Review*), 489
Oleic Acid, Pure, J. B. Brown and G. Y. Shinowara, 379
Optical: Lenses Moulded from Plastic Material, 336; Contact, Lord Rayleigh, 781
Opicinus de Canistris: Weltbild und Bekenntnisse eines Avignonesischen Klerikers des 14 Jahrhunderts, R. Salomon, Mit Beiträgen von A. Heimann und R. Krautheimer. Textband; Tafelband (*Review*), 131
Orchestration, Adjustable Resonators and, Dr. E. G. Richardson, 157
Oregon, Mammals of, V. Bailey, 554
Organic: Compounds, Analysis of, [1837], 165; Oxides, Dissociable, C. Dufraisse and R. Priou, 300; Compounds: Elementary Analysis of, Semimicro-Methods for the, Prof. E. Sucharda and Dr. B. Bobranski. Translated by Dr. G. W. Ferguson (*Review*), 392; Preparation and Identification of, An Introduction to the, Prof. R. D. Coghill and J. M. Sturtevant (*Review*), 652
Orionids, Leonids and Geminids in 1936, Observation of, K. Komaki, 201
Ornithological Society [1837], 727

Orthite in some Victorian Granitic Rocks, G. Baker, 1031
Osaka University, Physics Research at, 242
Osphradium in Gastropoda, A Possible Function of the, G. C. E. B. Hulbert and Prof. C. M. Yonge, 840
Ostrea edulis, Metamorphosis of the Larva of, H. A. Cole, 413
l'Oubangui, Les rites secrets des primitifs de, A. M. Vergiat (*Review*), 611
Ovalbumin in Urea Solvent, Dissociation of, Prof. J. W. Williams and Dr. C. C. Watson, 506
Ovarian Extracts, Androgenic activity of, Dr. A. S. Parkes, 965
Overhead Transmission Lines, Lightning and, 201
Ovulation, Experimental Induction of, with Progesterone, Dr. H. Zwarenstein, 112
Oxford : University : Arctic Expedition, 1935–36, A. R. Glen, 10 ; Dr. S. Flexner appointed Eastman visiting professor for 1937–38, 39 ; Expedition to North-East Land, 1935–36, Biological Work of the, D. B. Keith, 55 ; conferment of an honorary doctorate on Dr. J. D. Pollock, 208 ; C. N. Hinshelwood appointed Dr. Lee's professor of inorganic and physical chemistry, 226 ; 257 ; H. Cairns appointed Nuffield professor of surgery and R. R. Macintosh Nuffield professor of anæsthetics, 257 ; Appeal, 276 ; and Present Needs in Science, 303 ; 365 ; Education at, [1837], 383 ; Inauguration of an Ultra-Centrifuge in, 402 ; Sir Arthur Salter elected independent M.P. ; conferment of an honorary doctorate on Prof. The Svedberg ; H. W. Thompson appointed demonstrator in chemistry ; Prof. N. V. Sidgwick reappointed reader in chemistry ; R. S. Creed and Dr. C. G. Douglas demonstrators in physiology, T. C. Keeley demonstrator in physics, Dr. R. L. Vollum demonstrator in pathology, E. Whitley demonstrator in biochemistry, and J. Z. Young demonstrator in zoology, 426 ; H. M. Sinclair elected Radcliffe travelling fellow in medicine for 1937, 520 ; Dr. J. A. Douglas appointed professor of geology, 539 ; 560 ; Sir William Beveridge made master of University College, 619 ; 643 ; Extension of Scientific Buildings, Dr. A. S. Russell, 664 ; Imperial Forestry Institute, 731 ; Prof. T. G. B. Osborn appointed Sherardian professor of botany, 746 ; 770 ; Dr. J. L. Stocks elected an honorary fellow of St. John's College, 770 ; G. R. Girdlestone appointed Nuffield professor of orthopædic surgery, Prof. J. A. Gunn Nuffield professor of therapeutics, and Dr. J. C. Moir Nuffield professor of obstetrics and gynæcology ; C. G. T. Morison re-elected reader in soil science, J. H. C. Whitehead elected lecturer in mathematics, R. L. Hall lecturer in economic science, Dr. D. A. Jackson and G. D. Amery lecturer in the history and economics of agriculture, 811 ; E. J. Bowen and J. W. Wolfenden appointed demonstrators in chemistry, and Dr B. G. Maegraith demonstrator in pathology ; M. A. Jennings elected Schorstein research fellow in medicine, 896 ; Dr. A. G. Gibson appointed Nuffield reader in morbid anatomy, Prof. H. J. Paton White's professor of moral philosophy, and M. L. Jacks director of the department of education, 938 ; E. S. Duthie appointed demonstrator in Pathology ; Prof. P. Jacobsthal appointed reader in Celtic Archæology, 1079 ; conferment of honorary doctorates on Rt. Hon. W. G. A. Ormsby-Gore, Hon. R. H. Brand, Sir Herbert Baker, Prof. W. Nernst and Dr. G. P. Gooch ; Prof. J. H. Hutton appointed Frazer lecturer in Social Anthropology for 1938, 1122
Oxidation of Metals giving Two Oxides, Introduction to the Kinetics of the, G. Valensi, 82
Oxide Films on Copper and Iron, Measurements of, Dr. U. R. Evans and Dr H. A. Miley, 283
Ozone from Air and from Oxygen, Problem of the removal of, E. Briner and E. Perrottet, 1031 ; very dilute, a method of analysing, E. Briner and E. Perrottet. 1031
Oxonium Compounds, Raman Spectra of, M. Wolkenstein and Prof. J. K. Syrkin, 288
Oxygen : at the Limit of the Solar Spectrum, Absorption of, L. Herman, 813 ; Evolved by Isolated Chloroplasts, R. Hill, 881
Oysters, English Native, *O. edulis*, Maturity and Fecundity of One-Year-Old, J. M. Dodd, J. McCloy, H. C. Davies, F. B. J. Edmonds, and Prof. J. H. Orton, 108
Ozakian in Greenland, Question of the, L. Koch, 728
Ozanam (J. A. F.), [1773–1837], 812
Ozone, Correlation of, with Atmospheric Phenomena, A. R. Meetham, 933

Painting in Enamel, Chemistry and the Art of, [1837], 937
Paintings, The Physics and Chemistry of, F. I. G. Rawlins (*Review*), 864
Paints, Protective, A. Vila, and others, 891
Palæarctis, On the Principles of Zoogeographical Division of the, as a Basis of a Study of Types of its Ornithofauna, Dr. B. K. Stegmann, 493
Palæogeography, Aspects of (*Review*), 902
Palaogeographie und Tektonik, Prof. F. Kossmat (*Review*), 902
Palæolithic : Portraiture, Dr. H. Kuhn, 33 ; Implements from Bombay, Exhibition of, 1100
Palestine : Electric Supply in, 105 ; Folk Museum, Appeal for the, 707
Palygorskites, Characteristics of the, H. Longchambon, 208
Panus stypticus (Bull.) Fries, Interfertility Phenomena of the American and European Forms of, Ruth Macrae, 674
Papain, Natural, Enzymic Properties of, M. Frankel, R. Maimin, and B. Shapiro, 249
Papaver, *Crepis* and *Tussilago*, Causes of Pre-Floral and Post-Floral Movements of Peduncles and Scapes in, V. M. Katunskij, 40
Papers, Book and Record, Deterioration of, T. O. Jarrell, J. M. Hawkins, and F. P. Veitch, 890
Papuan : Pygmies and Art (*Review*), 389 ; Insect Fauna, Origin of the, Miss L. Evelyn Cheesman, 1094
Paradise Fish, Melanophores of the, G. Tomita, 377
Paraguay, Establishment of a Ministry of Health in, 408
Paris : Academy of Sciences : Prize Awards for 1936 of the, 161 ; Prize award for 1936 of the, 205 ; Prof. G. Bouligand elected *correspondant* of the section of mechanics, 322 ; J. Chazy elected a member of the, 442 ; Prof. S. A. Waksman elected a *correspondant* of the, 503 ; Dr. S. Flexner elected a foreign associate of the, 583 ; to Brussels Railway, [1837], 853 ; Exhibition, Floodlighting and Broadcasting During the, 918 ; Prof. A. Chevalier elected a member of the, 1063
Parkes Memorial Prize, award of the, to Major E. F. W. Mackenzie, 242
Parliamentary Science Committee, 750
Particle Observers, Equivalent, Prof. L. Page, 281
Particles, High-Speed, Specific Ionization by, M. G. E. Cosyns, 802
Passenger Trains, Air Resistance of, F. C. Johansen, 206
Pasteur Institute of Southern India, Annual Report, 624
Patent Office Library, 875
Patient, The, and the Weather, Dr. W. F. Petersen, with the assistance of Margaret E. Milliken. 3 Vols. (*Review*), 90
Peace : International, Promotion of, 483 ; Science and, 979 ; Problems, Science and, 993
Peach Twigs, Transpiration of, Effects of Oil Sprays on the, G. D. B. de Villiers and S. M. Naudé, 167
Peary : Prof. W. H. Hobbs (*Review*), 263 ; The Man and the Explorer, Prof. F. Debenham (*Review*), 263
Peat-Compressing Press, A, [1837], 1121
Pediculopsis graminum Reut. (Acarina, Tarsonemidæ), Reproductive Behaviour and Haploid Parthenogenesis in, K. W. Cooper, 729
Peking Man : The Fifth Skull of, W. C. Pei, 109 ; Mandibles of, 120 ; The New Skulls and the Evolutionary Problem, 261
Peltier's Comet (1936, *a*), Emission of CO+ Bands in the Head of, J. Dufay, Mlle. Marie Bloch, and J. Ellsworth, 644

Pendulum for Ships, Edge's [1837], 1122
Peptidase Activity, Dilatometric Ultra-Micro-Estimation of, Dr. K. Linderstrøm-Lang, 713
Perkin Medal of the American Section of the Society of Chemical Industry, Award of the, to Dr. T. Midgley, 317
Permanganates and Plant Growth, M. E. Webster and Dr. I. M. Robertson, 71
Permonophosphoric Acid, G. Toennies, 807
Peronospora Schleideniana W. G. Sm., Germination of Oospores of Onion Mildew, R. McKay, 758
Peru: Cañete Valley, Archæological Exploration in, Prof. A. L. Kroeber, 1073
Peruvian Manuscript, A, 514
Pest and Plant, A. G. Bebbington and W. Allen, 377
Petroleum: and Petroleum Products, H. C. Fowler and others, 36; Refinery Engineering, Prof. W. L. Nelson (*Review*), 92; Refining of (*Review*), 92; Research, Organization in, J. H. Vermuelen; W. C. Asbury and D. A. Shepard, 361; Lubricating Oils, Molecular Distillation of, R. Lyth, 374; Technologists, Institution of, Col. S. J. M. Auld inducted as president; presentation of the Redwood medal to H. Ricardo, 503
Pharmacology, A Manual of, late Dr. W. E. Dixon. Revised by Dr. W. A. M. Smart. Eighth edition (*Review*), 737
Pharmacopoeia, The Extra, W. Martindale. Twenty-first edition. In 2 Vols. Vol. 1 (*Review*), 780
Phenological Report for 1935, I. D. Margary, 321
Philosophy: of Religion, The, *versus* the Philosophy of Science, A. Eagle (*Review*), 463; American, Contemporary (*Review*), 904; Physical Science and, Sir Arthur Eddington, 1000; Prof. P. A. M. Dirac, 1001; Prof. W. H. McCrea, 1002; Prof. J. B. S. Haldane, 1003; Dr. H. Jeffreys, 1004; Dr. N. R. Campbell, 1005; Prof. L. N. G. Filon, Prof. W. Peddie, Prof. R. A. Sampson, 1006; Prof. C. G. Darwin, 1007; G. J. Whitrow, 1008; Fr. W. McEntegart, Dr. H. Stafford Hatfield, Prof. G. Dawes Hicks, 1009
Phospholipid Synthesis during Fat Absorption, C. Perrier, N. Santangelo, Prof. E. Segrè, C. Artom and G. Sarzana, 1105
Phosphonitril Radical, P. N. Existence and the Stability of the, and the Synthesis of Phosphorus Dichloronitride, H. Moureu and G. Wetroff, 208
Phosphorescence of the Sea, Dr. R. E. D. Clark, 592; Dr. J. Weir French, 804
Phosphorescent Glasses, M. Curie, 427
Phosphors: in a Neon Discharge Tube, Excitation of, A. Ruttenauer, 160; C. C. Paterson, 420
Phosphorus: Atoms in Plants and Seeds, Exchange of, Prof. G. Hevesy, Dr. K. Linderstrøm-Lang, and C. Olsen, 149; in Animals, Metabolism of, G. Hevesy, O. Chiewitz, and G. Hevesy, 343; in Animal Tissues, Rate of 'Organification' of, C. Artom, G. Sarzana, C. Perrier, M. Santangelo, and Prof. E. Segrè, 836; Metabolism in Normal, Rachitic and 'Treated' Rats, Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and J. de Vries, 1068
Photographic: Extinction, Apparent Character of a Variation of a, with Atmospheric Humidity, P. Rossier, 209; Plates, Measurement of, by projection, G. F. Kellaway, 1116
Photosensitized Reactions involving Deuterium, Prof. H. S. Taylor and others, 933
Physical: Society's Exhibition Catalogue, 65; Society, award of the Duddell medal to Prof. W. G. Cady, 243; Constants and Some Curious Coincidences, Prof. J. Satterly, 290; Training and National Well-being, 647; Science and Philosophy, Sir Arthur Eddington, 1000; Prof. P. A. M. Dirac, 1001; Prof. W. H. McCrea, 1002; Prof. J. B. S. Haldane, 1003; Dr. H. Jeffreys, 1004; Dr. N. R. Campbell, 1005; Prof. L. N. G. Filon, Prof. W. Peddie, Prof. R. A. Sampson, 1006; Prof. C. G. Darwin, 1007; G. J. Whitrow, 1008; Fr. W. McEntegart, Dr. H. Stafford Hatfield, Prof. G. Dawes Hicks, 1009
Physico-Chemical Tables (*Review*), 93
Physics: in Industry, Dr. Oplin, 146; of the Solid State: Fiftieth Anniversary of the Physical Society of Zurich, 255; in 1936, Prof. T. H. Osgood, 501; Industrial, Birmingham Conference on, Dr. H. R. Lang, 600; Law of, Geometrization of the, Y. Mimura, 893; Institute of, Annual Report for 1936; Election of Officers, 958; German (*Review*), 983; Quantum: and classical physics, analogy between the retarded potential of, E. C. G. Stueckelberg, 1031; establishment of the formula of retarded potential in, E. C. G. Stueckelberg, 1031
Physik, Deutsche, Prof. P. Lenard. In 4 Baden. Band 1: Einleitung und Mechanik (*Review*), 983
Physikalischen Untersuchungen, Technische Kunstgriffe bei, Prof. E. von Angerer. Dritte Auflage (*Review*), 9
Physiological Congresses, Permanent International Committee of, Prof. L. A. Orbeli appointed a member of the, 710
Physiology, Indian, Lieut.-Col. S. L. Bhatia, 640
Phytophthora erythroseptica Pethybr., Potassium Permanganate as an Aid to the Production of Asexual Fructification by, R. McKay, 802
Phytoplankton and the Herring, R. E. Savage and R. S. Wimpenny. Part 2, 382
Picts? Who Were the, Sir Herbert Maxwell, Bart., 115
Pigments Associated with the Fatty Tissues of Plants and Animals, Prof. I. M. Heilbron and A. E. Gillam, 612; 657
Pike, Horizontal Semicircular Canal in the, Effect of Unilateral Elimination of the, Dr. O. Lowenstein, 715
Piltdown Jaw, A. T. Marston, 103
Pinholes, Optical Experiments with, F. J. Hargreaves, 254
Pinus radiata in New Zealand, T. T. C. Birch; A. D. McGavock, 475
Pisum sativum: Linkage in Structural Hybrids in, Miss Caroline Pellew, 113; Segmental Interchange Lines in, Mrs. E. Sansome, 113
Pitchblende, Preparation of an Accurate Emanation Standard from, V. H. Matula, 301
Pithecanthropus—Man or Gibbon? Prof. W. E. Le Gros Clark, 721
Pituitary, Anterior, An Antiluteogenic Factor in the, J. Freud, 880
Place-Names: and their Study (*Review*), 445; of Warwickshire, The, J. E. B. Gover, A. Mawer, and F. M. Stenton, in collaboration with F. T. S. Houghton (*Review*), 445
Planetary Positions at Sunset in 1937, S. L. Walkden, 471
Plankton: Research and Sea Fisheries, 382; Collector, The Modern Centrifugal Pump as a, S. G. Gibbons and J. H. Fraser, 417
Plant: Growth, Permanganates and, M. E. Webster and Dr. I. M. Robertson, 71; Pathology in Devon and Cornwall, 146; Growth Hormones, Synthetic, E. M. Crook, Dr. W. Davies, and Miss Norma Elizabeth Smith, 154; Ashes from Auriferous Ground, New Analysis of, B. Němec, J. Babička, and A. Oborský, 301; Collecting on the Pribilof and Aleutian Islands, 1936, Isobel W. Hutchison, 327; Virus, An Air-borne, Dr. Kenneth M. Smith, 370; Diseases, Research on, An Introduction to, Prof. A. J. and Mrs. Riker, 404; Physiology: Fifty Years of (*Review*), 448; Principles of, An Introduction to the, Prof. W. Stiles (*Review*), 448; Hormones and Mineral Nutrition, G. S. Avery, jun., P. R. Burkholder, and Harriet B. Creighton, 481; Disease, Boron and the Control of, Dr. Winifred E. Brenchley, 536; Virus, An Air-borne, Dr. J. Caldwell; Dr. Kenneth M. Smith, 761
Plants: Immunity of, to Disease, Dr. E. J. Butler and others, 297; Disease Resistance in, 598; Poisonous to, J. F. Couch, 806
Plastic Reconstruction, The Technique of, Dr. H. L. H. H. Green, 759
Plastics for Use in Electrical Engineering, A. R. Dunton, 320
Pluto and the Neptunian System, Encounters between, R. A. Lyttleton, 516

Poliomyelitis, Acute, 503
Pollen: Grains, Spontaneous Chromosome Changes in, Miss Margaret Upcott, 153; Storage of, B. R. and M. L. Ruttle, 595
Polygons of similar attraction, R. Wavre and G. Bilger, 1031
Polymerization of Certain Substances, Kinetics of, Prof. H. Mark, 255
Polymetamorphic Rocks of the Valla Field Block, Unst, Shetland Islands, Metamorphic collection in the, Prof. H. H. Read, 976
Polyplacophora, Structure and Function of the Alimentary Canal of Some Species of (Mollusca), Vera Fretter, 561
Polyploid Plants, Production of, 292
Pontifical Academy of Science, 257
Population?: Whither, Sir William Beveridge; Dr. R. R. Kuczynski, 162; Trends, Dr. R. R. Kuczynski, 164; in Great Britain, The Trend of, 564; Some economic consequences of a declining, J. M. Keynes (Galton lecture), 1023
Port Erin, Marine Research at, 763
Portugal in 1936, Dr. L. Dudley Stamp, 162
Positrons from Radio Scandium, Dr. J. C. Jacobsen, 879
Post Office: and Broadcasting, Sir George Lee, 709; Speaking Clock in Great Britain, Dr. E. A. Speight and O. W. Gill, 892
Potassium: Iodobismuthates, Constitution of Solutions of, F. Gallais, 342; Permanganate as an Aid to the Production of Asexual Fructifications by *Phytophthora erythroseptica* Pethybr., R. McKay, 802
Potato: Virus Diseases of the, Prof. P. A. Murphy, J. B. Loughnane, and others, 75; Some Diseases of the, 118; Virus, An *F*-Type, in Australia, J. G. Bald, 674; Virus, Y, Acquired Immunity against the, Dr. A. N. Salaman, 924; Eelworm Investigations, J. Carroll, 1080
Potatoes, South American, and their Breeding Value, 200
Poverty: and Over-Taxation: The Way Out, Marquis of Tavistock, 619; Line, A Revised Estimate of the, R. F. George, 708
Powell, Rev. Baden, on the Dispersion of Light, [1837], 123
Power and Light for North Wales, Brig.-Gen. R. F. Legge, 726
Precious Stones, A Key to, Dr. L. J. Spencer (*Review*), 450
Precision Measurements with a Radial Deflection Oscillograph, J. J. Dowling and T. G. Bullen, 770, 1030
Pregnancy Urine Extract, Inhibition of the Gonadotropic activity of, by the serum of Rabbits injected with an extract of Male Urine, P. de Fremery and B. Scheygrond, 1015
Prehistoric Caves in Kent, 438
Prehistory of North Africa, Chronological Problems in the, R. Vaufrey, 432
Printing and Allied Trades Research Association, Opening of New Laboratories of the, 498
Priorities, A Programme of, 619
Prix internationaux du Tourisme, award of, to Mrs. Brangwyn and to Dr. Cloudesley Brereton, 103
Probability: Elements of, Prof. H. Levy and L. Roth (*Review*), 609; Theory and Applications, Dr. J. Neyman (*Review*), 609
Progesterone: Experimental Induction of Ovulation with, Dr. H. Zwarenstein, 112; Effect of, on Lactation in the Rat, Dr S. J. Folley and Dr. S. K. Kon, 1107
Prony's Absorption Brake, [1837], 601
Protein: Films, Dr. I. Langmuir, Dr. V. J. Schaefer, and Dr. Dorothy M. Wrinch, 516; Structure, X-Ray Interpretation of, Dr. W. T. Astbury, 641; 'Crystals' from Virus-Infected Plants, Structure Types of, Dr. J. D. Bernal and Dr. I. Fankuchen, 923
Proteins: in Cancer Diagnosis, Application of the Polarographic Effect of, Dr. R. Brdička, 330; Infra-Red Spectrum of the, Interpretation of the, F. Vlès and E. Heintz, 602; X-Ray Studies of, 641; Linkages in, Nature of the, Dr. Dorothy M. Wrinch, 718; Intramolecular Folding of, by Keto-Enol Interchange, Dr. W. T. Astbury and Dr. Dorothy M. Wrinch, 798; "Globular," the Cyclol Theory and the, Dr. D. M. Wrinch, 972
Proton-Neutron Exchange Interaction, Experimental test of the, H. J. Bhabha, 1021; 1103
Protons, Scattering of, by Protons, M. A. Tuve, N. P. Heydenburg, and L. R. Hafstad; G. Breit, E. U. Condon, and R. D. Present, 378
Protoperidinium, The Sub-Genus, Dr. T. H. Abé, 158
Prussian Academy of Science, Prof. H. Wieland elected a corresponding member of the physico-mathematical section, 624
Pseudo-Methæmoglobin, A New Blood Pigment, Dr. N. H. Fairley, 588
Psycho-Analysis and Social Psychology, Prof. W. McDougall (*Review*), 94
Psychology, Industrial, and the Modern World, Dr. C. S. Myers, 919
Psyllidæ, Scottish and other, Immature stages of some, K. B. Lal, 976
Public: Health: The Last Thirty Years in, Recollections and Reflections on my Official and Post-Official Life, Sir Arthur Newsholme (*Review*), 173; Manual of, Laboratory Practice, Prof. J. R. Currie and contributors (*Review*), 176; Analysts and other Analytical Chemists, Society of, election of officers, 442; Welfare and Modern History, Progressive Science in, 533
Puccinia graminis, Production of Uredia and Telia of, on *Berberis vulgaris*, Dr. Margaret Newton and Dr. T. Johnson, 800
Puerto Rican Prehistory, I. Rouse, 897
Pulitzer Prize for Science Reporters, awards of the, 873
Punjab, Erosion in the, 541
Purple, Visual: Scotopic Luminosity Curve and the Absorption Spectrum of, Dr. H. J. A. Dartnall and C. F. Goodeve, 409; in Solution, Bleaching of, Dr. G. Wald, 587
Pycnogonids from Puget Sound, Harriet I. Exline, 75
Pyruvic Acid, Infra-Red Absorption Spectrum and Molecular Structure of, P. Bayard, 342

Qualitative Analysis, Semi-Micro, Prof. C. J. Engelder, T. H. Dunkelberger, and Dr. W. J. Schiller (*Review*), 392
Quantitative: Analysis, A Textbook of, Prof. C. J. Engelder. Second edition (*Review*), 392; Organic Microanalysis of Fritz Pregl, Dr. H. Roth. Third English edition, translated by Miss E. Beryl Daw (*Review*), 453
Quartz, Plates of, Vibrations of, Cut in Various Planes around the Optical Axis of the Crystal, Ny Tsi-Zé and Shang Keng-Yi, 854
Quartzite, Transfusion of, Doris L. Reynolds, 515
Queen Mary, Machinery of the, J. Austin, 599
Quekett Microscopical Club: J. Ramsbottom elected an honorary member of the, 148; election of officers, 366

Racial: Theory and Cross-Breeding, A. M. Hocart, 415; Portraiture: A Sculpture's View (*Review*), 487; Crossing, The case for (*Review*), 1087
Radcliffe Travelling Fellow in Astronomy, Dr. H. Zanstra elected, 544
Radiation: Biological Effect of, Colloids and the, R. T. M. Hames, 32; Coherent Visible, Due to Fast Electrons Passing through Matter, I. Frank and I. Tamm, 939
Radiations, A Photochemical Antagonism of, G. Holst, 285
Radio: -active Disintegration of a Light Element, α-Particles from the, Dr. W. B. Lewis, W. E. Burcham and W. Y. Chang, 24; Fade-Outs, Solar Eruptions, and, 61; Research in India, Prof. S. K. Mitra, 62; Prof. M. Saha, 63; Waves, Interaction by Resonance of, Prof. V. A. Bailey, 68; Reception, Communal Aerials for, 188; Waves, Centimetre, C. E. Cleeton and N. H. Williams, 201; Fadings, Recent Solar Activity and, 228; Fade-Outs, Bright Solar Eruptions and, Magnetic Effects Associated with, A. G. McNish, 244; Waves, Reflection of, from the Middle Atmosphere, R. A. Watson Watt, A. F. Wilkins, and

E. G. Bowen, 277; 299; Frequency, Standards of, 363; -Elements in Chemical and Biological Research, Prof. F. A. Paneth, 439; Communication for the Student (*Review*), 451; activité, Madame Pierre Curie (*Review*), 528; -activity, Artificial, Produced by Means of γ-Rays, W. Bothe and W. Genther, 555; Compass, Automatic, H. Busignies, 642; -activity Induced, with Neutrons from Slow Deuterons, E. Bertl, Prof. R. Fürth, F. Obořil, and Dr. K. Sitte, 716; -active Substances, Thermal Precipitation of, Prof. F. A. Paneth and Dr. C. Rosenblum, 796; Waves, Resonance in the Interaction of, Prof. V. A. Bailey, 838; -activity Induced by Fast Neutrons according to the (*n*, 2*n*) Reaction, F. A. Heyn, 842; -Scandium, Positrons from, Dr. J. C. Jacobsen, 879; Fading and Solar Eruptions, Dr. R. S. Richardson, 889; -Frequency Technique (*Review*), 1087; -active Isotopes of Copper, Dr. E. A. Oeser and J. L. Tuck, 1110; -activity produced by Gamma Rays and Neutrons of high energy, W. Y. Chang, M. Goldhaber and R. Sagane, 962; Induced, of Silver with Neutrons from slow Deuterons, E. Bertl, Prof. R. Furth, F. Obořil and Dr. K. Sitte, 964; Artificial, produced by fast Neutrons and their inelastic collisions, J. Rotblat, 1110; Echoes, Around-the-World, A. C. Peterson, 1074
Radium: Beam Therapy and High-Voltage X-Rays, Prof. A. S. Eve and L. G. Grimmett, 52; Treatment in Great Britain, Prof. S. Russ, 699; Rays, Action of, on the Growth of Cells *in vitro*, Prof. L. Halberstadter and L. Doljanski, 841
Railway Traction Problems, Lord Monkswell, 764
Railways, British [1837], 521
Rainfall: British, 1935 (*Review*), 134; and Moon Phases in the Tropics, C. H. B. Williams, 244
Ram, Maynard Ganga, prizes, award of, to T. A. Miller Brownlie and Prof. R. S. L. Jai Chand Luthra, 958
Raman: Spectrum of Benzene Vapour, S. Bhagavantam and Dr. A. V. Rao, 114; Spectra: of Oxonium Compounds, M. Wolkenstein and Prof. J. K. Syrkin, 288; Excitation of, with the Aid of 'Optical Catalysers', R. V. L. Hartley, 329; Effect as a Method of Analysis of Amine Acid Solutions, N. Wright and W. C. Lee, 551; Spectrum of Monodeuteroethylene, J. M. Delfosse, J. C. Jungers, G. Lemaitre, Y. L. Tchang and Prof. C. M. Manneback, 1111
Randomness in a Series of Numerical Observations, Tests for, W. O. Kermack and A. G. M'Kendrick, 560
Ranikot Sea, Extent of the, Lieut.-Col. L. M. Davies, 414
Rare: Earths, Bivalent, Fluorescence of the Prof. K. Przibram, 329; Earth Elements, a Sensitive Method for Detecting Traces of, M. Servigne, 728; Earths, Colour Reactions of, with Alkaloids, F. M. Šemiakin, (3), 939
Rasori, Giovanni (1766–1837), 644
Rat, Lactation in the, Effect of Progesterone on, Dr. S. J. Folley and Dr. S. K. Kon, 1107
Rats, Normal, Rachitic and 'Treated,' Phosphorus Metabolism in, Dr. M. J. L. Dols, Prof. B. C. P. Jansen, Prof. G. J. Sizoo and J. de Vries, 1068
Rattus norvegicus, Linkage Studies of, Helen D. King and W. E. Castle (2), 729
Ray Society, election of officers, 503
Rays Entering the Eye Pupil at Different Points, Luminous Efficiency of, Dr. W. S. Stiles, and B. H. Crawford, 246
Readers Digest prize, award of the, to Prof. W. M. Krogman, 107
Reading, National Institute for Research in Dairying, Annual Report for 1935, 364
Reagents for 'Spot' Tests and Delicate Analysis, The B.D.H. Book of, Fifth and enlarged edition (*Review*), 176
Realgar in Wookey Hole, Somerset, Dr. J. Newton Friend, 72
Realism, Personal, Prof. J. B. Pratt (*Review*), 904
Reaping Machine, McCormick and the, Prof. J. Hendrick, 197
Recreation, Influence of, on Sedentary Workers, Dr. W. Missiuro, 932
Red Sea, Four Molluscs Rarely Recorded from the, Dr. C. Crossland, 31
Refractivity Intercept, The, S. S. Kurtz, jun., and A. L. Ward, 34
Registrar-General's Statistical Review of England and Wales for 1934, 146
Resistance to Motion of Obstacles in Air, Influence of Pressure on the, J. Luneau, 82
Resistances, Automatic Starting, 76
Resolving Power, Effect of the Penetration of X-Rays on the, Prof. V. Dolejšek and J. Klein, 886
Resonators, Adjustable, and Orchestration, Dr. E. G. Richardson, 157
Respiration in Tropical Fruits, Dr. C. W. Wardlaw and Dr. E. R. Leonard, 475
Resuscitation, Experiments in, 441
Retinal Centre as an Amplifier of Potential Differences, The, Prof. R. Granit, 719
Retinitis Pigmentosa, Carotene Therapy of, Dr. E. M. Josephson and Dr. M. Freiberger, 155
Rhine, New Power Station on the, 1101
Rhodes Scholars, Distribution of, 39
Rhodesia, Northern: Native Policy in, Sir Hubert Young, 360: Native Agriculture in, Trapnell, 847
Rice: in England, Cultivation of, [1837], 165; dwarfing in, Genes for, B. S. Kadam, 1070
River Water, Clarification of, Prof. J. Milbauer, 119
Road Aggregate, Shape of, 379
Rockefeller: Foundation, grants for research, 442; travelling medical fellowships, 667; Foundation China Programme, 751; and Philanthropy, W. Connely, 1075
Roman: Sussex, 20; Britain and the English Settlements, Prof. R. G. Collingwood and J. N. L. Myres (*Review*), 213; Orient, The, and the Far East, Prof. C. G. Seligman (Lloyd-Roberts lecture), 554
Rømer's, Ole, and Fahrenheit's Thermometers, Dr. Kirstine Meyer (née Bjerrum), 585; Dr. J. Newton Friend, 586
Rontgen Institute at Munich, foundation of a, 960
Root: Nodules, Leguminous Excretion from, Dr. G. Bond, 675; Systems, T. K. Pavlychenko, 678; -growth in the Soil, a device for the observation of, Dr. G. H. Bates, 966
Rothamsted: Experimental Station: Dr. C. R. Marshall appointed for honey research at the, 23; Report for 1935, 37; and Agriculture, Annual Inspection of the Plots; messege from Prof. H. E. Armstrong, 1027
Rous Fowl Sarcoma, Nature of the Causative Agent of the, Prof. E. M. Fraenkel and Dr. C. A. Mawson, 282
Roux, Dr., On the Removal of Cataract, [1837], 81
Royal: Academy, Rural England at the, Dr. Vaughan Cornish, 786; Aeronautical Society, awards of the, 751; Air Force, New Equipment of the, 317; Anthropological Institute, award of the Wellcome gold medal to Dr. C. Kingsley Meek and the Rivers memorial medal to Dr. E. E. Evans-Pritchard, 831; Asiatic Society: conferment of honorary membership on Prof. J. Bloch, Prof. C Brockelmann, and Prof. J. P. Vogel, 442; award of the Burton memorial medal to Sir Arnold T. Wilson, 667; Astronomical Society: award of the gold medal to Dr. H. Jeffreys, 107; election of officers, 322; election as associates of Dr. B. Lyot, Prof. J. H. Oort, and Prof. Shajn, 916; Botanic Gardens, Kew, A Film of the, 706; Botanical Gardens and Empire Botanists, Sir Arthur Hill, 422; Central Asian Society, award of the Lawrence memorial medal to Sir Charles Bell, 279; College of Surgeons, [1837], 299; Geographical Society, [1837], 811; awards, 834; [1837], 853; Institute of Public Health, award of the Harben gold medal to Sir Frederick Gowland Hopkins, 795; Institution: [1837], 769; Anniversary Meeting, election of officers, 792; Meteorological Society: R. T. Zock elected a foreign member, 148; election of officers, 190; Society: election of new fellows, 829; [1837], 895; of Edinburgh: election of fellows, 407; award of the Gunning Victoria Jubilee prize to Prof. C. G. Darwin and of the Makdougall-Brisbane

prize to Dr. E. M. Anderson, 442; Veterinary College and Hospital, New Governing Body, 710; Society of Arts, Achievements of the, 958; award of the Albert Medal to Lord Nuffield, 960; Astronomical Society [1837], 975; Observatory, Greenwich, Annual Visitation, 1026; Society, election of the Earl of Athlone as a fellow and of Prof. A. Krogh, Prof. O. Meyerhof and Prof. H. N. Russell as foreign members, 1098
Rubber Solids, Surface Temperature of, and the Formation of the Beilby Layer, Dr. F. P. Bowden and T. P. Hughes, 152
Rumanian Society of Genetics and Eugenics, A Royal, Founded, 752
Ruminants, Horned, of North America, C. Frick, 1073
Russia, Northern, Heat and Power Station in, 581
Russian: Railway Transport, 833; Trans-polar Flight, 1100
Rutley's Elements of Mineralogy. Twenty-third edition, Prof. H. H. Read (*Review*), 459

Sahara, Nigeria and the, Dr. J. D. Falconer, 199
St. Kilda Papers, 1931, 1050
Salmon, Yolk of the Egg of, F. R. Hayes and D. M. Ross 333
Salvador Earthquake of Dec. 20, 19
Samarium, Divalent, Red Fluorescent Band of, Prof. K. Przibram, 523
Samuel's Theory of Linkage, Spectrum of Mercury Chloride (HgCl) and, Dr. K. Wieland, 590
Sand Devils, W. D. Flower, 201
Sands, Clays and Minerals, November, 65
Saprolegnia terrestris n.sp., with Some Preliminary Observations on Victorian Soil Saprolegniales, Isobel Cookson, 125
Saprophytic Flagellatæ, Assimilation of Different Organic Substances by, Prof. E. G. Pringsheim, 196
Savage Civilization, T. Harrisson (*Review*), 568
Scenery: The Preservation of our, Essays and Addresses, Dr. Vaughan Cornish (*Review*), 459
Science: *Abstracts*, Index Nos. of Vol. 39, 582; New Conceptions of, University of Heidelberg and, 98; Frustration of, J. Pelseneer, 105; Masters Association, Annual Meeting, 121; Sir Cyril Ashford elected president, 122; Civilizing, A. L. Bacharach (*Review*), 129; in Recent Years (*Review*), 216; March of, A First Quinquennial Review, 1931–35, Various Authors (*Review*), 216; and Social Ethics, 276; Teaching, An Experiment in, Prof. A. J. Riker, 404; and Building Exhibition, 421; and Industry in the Eighteenth Century (*Review*), 443; Industry and Society, 525; Popularization of, Watson Davis, 578; and Politics in India: A Contrast, 605; Social Responsibilities of, 689; Fights Death, D. S. Murray (*Review*), 864; Logical Structure of, Prof. A. C. Benjamin (*Review*), 904; and Peace, 979; and Social Responsibility (*Review*), 981; stands for, What, Sir John Boyd Orr, Prof. A. V. Hill, Prof. J. C. Philip, Sir Richard Gregory, Bt., Sir A. Daniel Hall, and Prof. L. Hogben (*Review*), 981; and Peace Problems, 993; and Philosophy, Relations between, 993; and John Donne (*Review*), 1035; Museum, Television Exhibition at the, 1077; The World of, Dr. F. Sherwood Taylor (*Review*), 1089; teaching of, in the education of the citizen, Prof. L. Hogben, 1101; News a Century Ago, 39; 81; 123; 165; 207; 258; 298; 340; 383; 425; 479; 520; 601; 643; 685; 727; 769; 811; 853; 895; 937; 559; 975; 1029; 1079; 1121
Sciences, Exact, Bibliography of the (*Review*), 693
Scientific: and Technical Books, Recent, January 30, v; February 27, v; March 27, iii; April 24, v; May 29, v; June 26, v; Centenaries in 1937; Eng.-Capt. E. C. Smith, 12; and Learned Societies of Great Britain and Ireland, Official Year-Book of the. Fifty-third annual issue (*Review*), 51; Papers, Composition of, 64; Management, Federal Council on, election of officers, 147; Freedom, Resolution on, of the American Society of Naturalists, 185; and Technical Papers, Preparation of, Prof. S. F. Trelease and Emma Sarepta Yule. Third edition (*Review*), 217; Research, Inter-Imperial Co-operation in, 304; Worthies and Events Commemorated on Postage Stamps, J. G. Pilkington, 331; Management and Economic Problems, Major L. R. Urwick, 364; Research, Librarianship in Relation to, 429; Progress, (Sir Halley Stewart lectures, 1935), Sir James Jeans and others (*Review*), 463; and Industrial Research, Department of Report for 1935-36, 533; Unions, The International Council of, 697; Research in Spain, Prof. C. S. Gibson, 719; Unions, International Council of, Third General Assembly, 869; Prof. C. Fabry elected president, 870; Workers, Association of, Sir Frederick Gowland Hopkins elected president of the, 921
Scottish: Marine Biological Association, Report for 1935–36, 514; Technical Colleges, 581; Science in the English Industrial Revolution, The Theoretical Leadership of, Prof. L. Hogben, 918
Scripps Institution of Oceanography, 242
Sculptor's Odyssey, A, Miss Malvina Hoffman (*Review*), 487
Sea: Dayak Textiles, Prof. C. G. Seligman (*Review*), 530; Breezes, Dr. R. C. Sutcliffe, 636; -Trout, Migration of, S. Żarnecki, 1114
Seeber, Dr., in South Africa, K. H. Barnard, 474
Selaginella, Correlation phenomena and Hormones in, Dr. S Williams, 966
Selenium: Liquid, Coefficient of Viscosity of, S. Dobinski and J. Wesolowski, 385; Elastic Properties of, K. H. Meyer and J. F. Sievers, 764; Rubber-like elasticity in, K. H. Meyer and J. F. Sievers, 977
Sensibility Constants of Receivers of Radiant Energy, Determination of the, by Means of Scales of Colour Indices and of Effective Wave-lengths, P. Rossier, 209
Sera and their proteins, Optical activity of, separated by the acetone method in the cold, C. Achard, A. Boutaric and Mme. Madeleine Roy, 1080
Serpentine, Condobolin-Trundle District, N.S.W., Probable Late Silurian Age of, H. G. Raggatt, 603
Sex: Dr. B. P. Wiesner (*Review*), 9; Chromosomes: Genetical and Mechanical Properties of (3) Man, P. C. Koller, 561; Characters, Primary and Secondary Stimulative and Inhibitive Induction in the Development of, E. Witschi, 645
Shabti Figures (*Review*), 486
Shabtis Illustrated by the Egyptian Collection in University College, London: with Catalogue of Figures from many other Sources, Sir Flinders Petrie (*Review*), 486
Shakespeare's Universe, Prof. J. Dover Wilson, 792
Sheep: Artificial Thallium Moult in, Prof. N. A. Iljin, 104; Tapeworm, Common, Attachment of the Sheep Hookworm to the, D. G. Davey, 250; Hookworm, Attachment of the, to the Common Sheep Tapeworm, D. G. Davey, 250
Sheffield University: J. A. Wragg appointed assistant to Dr. W. A. Timperley; resignation of R. Ibbotson, 520; grant from the Rockefeller Foundation to the dept. of pharmacology, 560; further gift by Sir Robert Hadfield, Bart., 832
Shillibeer's Voltaic Battery, [1837], 425
Silene maritima and *S. vulgaris*, Researches on, E. M. Marsden-Jones and Dr. W. B. Turrill, 721
Silica: Fused, The 2·73μ Absorption Band of, Dr. J. W. Ellis and Dr. W. K. Lyon; Dr. D. G. Drummond, 70; and Glass, Polished, Surface layer of, with further studies on optical contact, Lord Rayleigh, 1123
Silicon Pentoxide (Si_2O_5), Two-Dimensional Crystals of, N. A. Shishacow, 927
Silver: Haloids, The Dependence of the Thermal Expansion Coefficients of, on Temperature, P. G. Strelkov, 803; Difluoride, Magnetic Properties of, E. Gruner and W. Klemm, 1024
Sinanthropus pekinensis: Mandibles of, Prof. F. Weidenreich, 120; The New Discovery of Three Skulls of, Dr. F. Weidenreich, 269

Singapore, Fauna of, M. W. F. Tweedie and others, 291
Singing in the Wilderness: A Salute to John James Audubon, D. C. Peattie (*Review*), 776
Sittannavasal, Cave Temple at, Technique of the Painting Process in the, S. Paramasivan, 114
Skey on Muscular Fibre, [1837], 298
Smeatonian Society of Civil Engineers, The, S. B. Donkin, 187
Smith, Sir Grafton Elliot, and Work on Early Man in China, W. C. Pei, 192
Smithsonian Institution, Report for Year Ended June 30, 1936, 665
Smoke: and Dust Emission from Chimneys, Prevention of, 138; Reducing Grates for Domestic Use, 405
Snake Nut Tree of Guiana, [1837], 975
Snakes of Maryland, Dr. H. A. Kelly, A. W. Davis, and H. C. Robertson, 932
Snow: International Commission of, 63; Nature of, G. Seligman, 186; 1090;
Snowshoes, D. S. Davidson, 1114
Social: Ethics, Science and, 276; Problems, Science and, 403; Hygiene To-day, H. E. Garle (*Review*), 464; Services, Public, 500; Mind of the Individual, K. C. Mukherji, 641; Responsibilities of Science, 689; Adjustment, The Science of, Sir Josiah Stamp (*Review*), 735; Sciences, A Programme for the, R. Brightman (*Review*), 735; in Human Knowledge, The place of the, Sir William Beveridge, 1117
Société Astronomique de France (1887–1937), 624
Society, Science, Industry and, 525
Sodium Lamps for Lighting Tennis Courts, 321
Soil: Problems, Unsolved (*Review*), 171; Surveyors' Executive Committee, Report of Third Correlation Tour, 544; Drift in South Australia, F. N. Ratcliffe, 580; Nitrogen Transformation in the, Prof. N. R. Dhar, 894
Soils, Base Exchange Capacity and Clay Content of, Dr. R. L. Mitchell and Dr. A. Muir, 552
Solar: Corona, Some Polarization Data of the, Dr. W. M. Cohn, 29; Eruptions: and Radio Fade-Outs, 61; Bright, Abnormalities of the Ionosphere and, R. Bureau, 110; Radiation at Calcutta, Prof. P. N. Ghosh, Dr. A. C. Ukil, and M. K. Sen, 159; Activity and Radio Fadings, Recent, 228; Eruptions, Bright, and Radio Fade-Outs, Magnetic Effects Associated with, A. G. McNish, 244; Activity, Comparative Variation of the Anomalies of Barometric Pressure and the, L. Petitjean, 300; and Magnetic Conditions Associated with Recent Auroras, The, Rev. J. P. Rowland, 680; Eclipse, The Total, of June, 1937, 698; Activity and Auroras, Recent, Eigenson and Gnevishev, 709; Heaters in California, Prof. F. A. Brooks, 794; Eruptions, Radio Fading and, Dr. R. S. Richardson, 889; Eclipse of December 13-14, 1936. Fall in air temperature during the, R. C. Hayes, 967; Total, of June 8, 993; Prominences, Motion Pictures of, R. McMath, 1013; Eclipse, Total, of June 8-9, 1047
Solutions of Alcohols in Ether or Dioxan: Oxanium Formation, Absorption Spectra in the Near Infra-Red of, R. Freymann, 208
Sorghum, Hybrid Vigour in, R. E. Karper and J. R. Quinby, 1115
Sotheran's Bibliotheca Chemico-Mathematica. Second supplement. 2 Vols. (*Review*), 693
Sound: A Standard Source of, and the Measurement of Minimum Audibility, Prof. E. N. da C. Andrade and R. C. Parker, 384; Propagation of, Effect of Turbulence on the, H. Dahl and Dr. O. Devik, 550; Velocity in Liquids, Dispersion of, B. V. Raghavendra Rao, 885
South: Africa, National Botanic Garden of, F. W. Thorns appointed curator of the, 106; African: Herbage Crops, 542; Institute for Medical Research, Annual Report for 1935, 665; -hampton University College, Dr. N. K. Adam appointed professor of chemistry in, 479; Australia, Soil Drift in, F. N. Ratcliffe, 580; -Eastern Union of Scientific Societies: Annual Congress at Hastings, 1120; Dr. J. S. Huxley elected president for 1938, 1121
Soviet: Russia, Supply of Vitamins in, Prof. P. V. Golovin, 281; Arctic Exploration, 321; Expedition to the North Pole, 955; 990
Spain, Scientific Research in, Prof. C. S. Gibson, 719
Special: Areas: (England and Wales), Third Report of the Commissioner for the, 1; The Social Opportunity in the, 1; Act, 539; Libraries and Information Bureaux, Association of, Sir Harry Lindsay nominated as president of the, 624; Areas, The, and the Location of Industry: Industrial Survey of South Wales, 899
Species, Insular and Continental, An Evolutionary Analysis of, A. C. Kinsey, 645
Spectrographic Research, Sources of Inaccuracies in, Dr. E. J. B. Willey, 758
Spectrophotometry, Time Effects in, W. M. H. Greaves, 254
Spectroscope, The, and the Atom, Prof. A. Fowler (Thomas Hawksley lecture), 95
Sperm Whale at the Natural History Museum, 319
Sphærium japonicum biwaense Mori, A Freshwater Bivalve (4), Dr. K. Okada, 200
Sponges of the Panama Canal, Dr. M. W. de Laubenfels, 594
Spoon Gauge, A Sensitive Adaptation of the, A. Lewis and Dr. D. W. G. Style, 631
Stammering, Incidence and Causes of, Dr. E. L. Hopewell-Ash, 1119; its cause and cure, 1119
Standardizing Scientific Method, Problem of Internationally, Miss M. L. Tildesley, 541
Staph. aureus, Growth of, Nicotinic Acid and the, B. C. J. G. Knight, 628
Star: Relations between the Colour Index and Effective Wave-length of a, P. Rossier, 209; Binary, Σ 2026, Orbit of the, Dr. R. v.d. R. Woolley and L. S. T. Symms, 848; Magnitude of a, a simplification in the calculation of the, relating to a receiver with two sensibility maxima, P. Rossier, 1031
Starling in the United States of America, The, Dr. W. E. Collinge, 491
Starlings, London, Effects of Traffic Disturbance and Night Illumination on, Prof. W. Rowan, 668
Stars: Photo-Electric Photometry of, J. D. Hall, 160; Variable, of Long Period, Change of Period in, T. E. Sterne and L. Campbell, 729; Nuclear Reactions in the, C. F. v. Weizsacker, 1116
Statesman's Year-Book, 1937, edited by Dr. M. Epstein (*Review*), 1089
Static Electricity on the Surface of Solid Dielectrics, Origin of, J. Strachan, 803
Statistical: Society, Anniversary Meeting of the, [1837], 480; Methods for Research Workers, Prof. R. A. Fisher. Sixth edition (*Review*), 737
Steam: Engine on Tyne Side, 1715-78, Dr. A. Raistrick, 748; Tables, N. S. Osborne, H. F. Stimson and D. C. Ginnings, 1024
Steel: Structures Research Committee. Final Report of the (*Review*), 5; Controlled Grain Size in, T. Swinden and G. R. Bolsover, 254; and Timber, Elementary Structural Problems in, Prof. C. R. Young. Second edition (*Review*), 349
Stellar: Constitutions and Systems (*Review*), 266; Problem of Three Bodies, Prof. E. W. Brown, 335
Stephenson Locomotive in Russia, A, [1837], 40
Sterckfontein Ape, The, Dr. R. Broom, 326
Stick Insects, Feeding Habits of, H. J. Sargent, 156
Stimulating Materials Obtained from Injured and Killed Cells, J. C. Fardon, R. J. Norris, Prof. J. R. Loofbourow, and Sister M. Veronita Ruddy, 589
Stone Age: Back in the, The Natives of Central Australia, Dr. C. Chewings (*Review*), 570
Stoney, Johnstone and Florence, studentships, award of, to Miss Mary Elizabeth King and Miss Joyce Laing, 835
Storage Battery Cars, 996
Stratosphere: Chemical Exploration of the, Prof. F. A. Paneth, 180; 220
Strength-duration Curves and the Theory of Electrical Excitation, W. J. Crozier, 729

Stromatoporoids: of the Lilydale Limestone (2), Elizabeth A. Ripper, 125; from Griffith's Quarry, Loyola, Victoria, Elizabeth A. Ripper, 1031; of the Buchan District, Victoria, Elizabeth A. Ripper, 1031
Structural Theory: Investigation and Rule (*Review*), 5
Submarine Telegraphy, Lyell's Forecast of, [1837], 1079
Sudbury Nickel Irruptive, W. H. Collins, 378
Suffolk, Geology of [1837], 425
Sugar-Cane Streak Disease, Economic effects of, A. P. D. McClean and R. H. Halse, 75
Sulphur: Vapour, Spectroscopic Study of the Constitution of, B. Rosen and Mlle. Nina Morguleff, 124; Phosphorus and Nitrogen in Plants Cultivated on a given Soil, Comparative amounts of, G. Bertrand and L. Silberstein, 166; Entropy of, E. D. Eastman and W. C. McGavock, 293
Sulphuric Acid, Concentrated, Minimum quantities of Catalysts having Maximum Effect in, J. Milbauer, 301
Sun, Magnetic Moment of the, Cosmic Rays and the, Dr. M. S. Vallarta, 839
Sunspots, Current, 752
Supraconducting Sphere in the Intermediate State, Electrical Conductivity of a, L. Shubnikov and I. Nakhutin, 589
Supraconductors of small dimensions, R. B. Pontius, 1065
Surfaces, Physical properties of, Dr. F. P. Bowden and T. P. Hughes (4), 1123
Suriname, Spirit Beliefs in, M. J. Herskovits and Frances S. Herskovits, 678
Swallows, Return of, to their Nesting Sites, A. W. Boyd and Dr. A. L. Thomson, 419
Swammerdam, Jan, 1637–80, Prof. F. J. Cole, 218; 287
Swanscombe Skull, appointment of a committee on the, 1048
Swaziland, Military Organization in, Hilda Beemer, 888
Symbols, Symmetry of, Prof. S. Goudsmit, 417
Syphilitic Sera, A Property of the Viscous Protein of, M. Doladilhe, 385
Systematics in relation to General Biology, formation of a committee on, 1014

Tables annuelles de constantes et données numériques de chimie, physique, biologie et technologie, Prof. E. Darmois. Années 1931 à 1934 (*Review*), 9
Tahiti, a Spanish Manuscript on, [1837], 1121
Tanganyika, Agriculture in, 362
Tanna Fault in Japan, Growth of the, H. Kuno, 254
Tantalum, A New Phenomenon in the Supraconducting Transition of, and of Tin, Dr. F. B Silsbee, R. B. Scott and Dr. F. G. Brickwedde, 325
Tasmania University, Dr. H. Gordon appointed lecturer in Botany in, 811
Tata, Lady. Memorial Fund, award of grants and scholarships, 1103
τ Tauri, Occultation of, B. M. Peek, 1074
Taxonomic Problem, A, J. S. L. Gilmour, 1040
Tea Plant, Pruning of the, J. R. Tubbs, 889
Teak Borer of Burma, D. J. Atkinson, 595
Technical Institutions, Association of Teachers in, Twenty-eighth Conference of, 936
Teeth, Man's Third Molar, Impaction of, B. Henry and Dr. G. M. Morant, 594
Telephone: Transmission, Standards of, W. H. Grinsted 543, Loudspeakers for Group Conversations, 544
Telephonique, International, Comité Consultatif, Proceedings of the Xth Plenary Meeting, Budapest, 3rd–10th September, 1934 (*Review*), 984
Telephony, International Co-operation in (*Review*), 984
Telescope Mirrors, Aluminizing of, Dr. J. Strong, 596
Television: Optics: an Introduction, L. M. Myers (*Review*), 94; Service, London, 280; Exhibition at the Science Museum, 1077
Telford, Memorial Tablet to, 995
Tellinacea (Lamellibranchiata), Ciliary Currents on the Gills of some, A. Graham, 384
Tellurium Molecule, Induced Predissociation of the, submitted to Intense Magnetic Fields, E. Olsson, 938
Temperature of a Room, Automatic Regulation of the, 335
Terbium Salts, Luminescence of Solutions of, A. Seidel, 248
Testing Materials, International Association for, London Congress, 765
Testosterone Propionate, Effect of, on Mating, Dr. H. A. Shapiro, 588
Tetrachlorethylene, Potential Constants of, J. Duchesne, 288; 634
Thames Barrage Proposal, 955
Theophrastus, Oak-galls in, Prof. G. Senn, 684
Thermo-Electric Pile, Experiments with the [1837], 727
Thermometry, Resistance, below 1·0°K., Dr. J. F. Allen and E. S. Shire, 878
Thornton, Robert (1768–1837), 124
Thyroid, Effect of Vitamin E Deficiency on the, Miss M. M. O. Barrie, 286
Tiergeographie des Meeres, Prof. S. Ekman (*Review*), 694
Tierwelt der Nord-und Ostsee, Die, Lief. 30, 920
Timber for Wood-Turning, 145
Timbers from Tropical and North Temperate Regions, A comparison of certain properties of, S. H. Clarke, 511
Time, The Measurement of, Prof. H. Dingle, 355
Tin: Persistent Currents in Supraconducting Single Crystals of, Influence of Magnetic Fields on, Prof. E. F. Burton and K. C. Mann, 325; Supraconducting Transition of Tantalum and of, A New Phenomenon in the, Dr. F. B. Silsbee, R. B. Scott and Dr. F. G. Brickwedde, 325; and other Metals, Investigation of Thin Layers of, P. J. Haringhuizen and D. A. Was (3), 602
Tissue Metabolism of Marine Cold-blooded Animals in Different Latitudes, Rate of, Prof. H. Munro Fox and C. A. Wingfield, 369
Titanium: Interstellar Ionized, Forbidden Transition in the Spectrum of, Dr. T. Dunham, jun., 246; Preparation of Thin Layers of, by the Electrolytic Method, M. Haissinsky and Mme. H. Emmanuel-Zavizziano, 686
Titanotheres from the Titus Canyon formation, California, C. Stock, 209
Tobacco: -Mosaic Virus Protein, Crystalline, Dr. W. M. Stanley, 203; -Mosaic Virus in Juice from Diseased Plants, Visible Mesomorphic Fibres of, R. J. Best, 628
Toepler *Schlieren* method, Observation of Ultra-centrifugal Sedimentation by the, A. Tiselius, K. O. Pedersen and Inga-Britta Eriksson-Quensel, 546
Tokyo, East, Subsidence of, Prof. N. Miyabe, 1024
Tomatoes: Polyploidy in, Physiological Effects of, Dr. A. C. Fabergé, 419; Haloe-spot of, Dr. C. L. Walton, 476
Tools of To-morrow, J. N. Leonard (*Review*), 134
Tops, simplest air-driven, Sedimentation Equilibrium in the, Prof. J. W. McBain and C. Alvarez-Tostado, 1066
Total Solar: Eclipse of June 19, 1936, Radio and Magnetic Observations at North-East Land during the, A. B. Whatman and R. A. Hamilton, 69; Eclipses, Air Temperature during, Dr. J. L. Haughton, 637
Town Planning and Decentralization, 440
Tracheomycoses in Plants, Fight against, G. Fron, 125
Tread Wheel, The, and Health [1837], 559
Trees, Ornamental, Care of, A. D. C. Le Sueur, 933
Triboluminescence, F. G. Wick, 603
s-Trideuterobenzene and the structure of Benzene, C. R. Bailey, A. P. Best, R. R. Gordon, J. B. Hale, Prof. C. K. Ingold, A. H. Leckie, L. H. P. Weldon and C. L. Wilson, 880
Trochus niloticus, Growth-rate of, Dr. H. S. Rao, 1023
Tropical Garden: The, its design, horticulture and plant materials, L. E. Kuck and R. C. Tongg (*Review*), 947
Tropics, Rainfall and Moon Phases in the, C. H. B. Williams, 244
Truth and Propaganda, Struggle between, Prof. M. Polanyi, 666
Tsetsefliegen, Die, Dr. F. Zumpt (*Review*), 822
Tsetse Flies. Water and Fat contents of, R. W. Jack, 31; Dr. C. H. N. Jackson, 674; of East Africa: The, a First Study of their Ecology, with a view to their Control, C. F. M. Swynnerton (*Review*), 734; Water and Fat content of, Dr. K. Mellanby, 883; Fly Problem, The (*Review*), 734

Turin, Royal Academy of Sciences, Progress in 1936, Prof. T. Cian, 503
Turner, Prof. Edward (1798–1837), 298
Tumour Growth, Effect of Tissue Extracts on, Dr. J. B. Murphy, 200
Tumours: Transplantable with Viruses, Dr. W. E. Gye and Dr. F. Pentimalli, 158; Transplantable, Influence of various Polycyclic Hydrocarbons on the Growth-rate of, A. Haddow, C. M. Scott and J. D. Scott, 342; Grafted, Influence of certain Plant Substances on the Growth of, M. Gatty-Kostyal, Mme. M. Paszkowska and Z. Zakrzewski, 687
Tunnels and Health [1837], 383
Tyrosine in Diseased Pedipalps, F. A. Bannister, 469

Uganda, Reactions in (*Review*), 214

No. 3505 SATURDAY, JANUARY 2, 1937 Vol. 139

The Social Opportunity in the Special Areas

IN his presidential address to the British Association at Blackpool, Sir Josiah Stamp pointed out that society and its institutions should now be learning that change is a continuous function, and that meeting it requires the development of an appropriate technique. This passage in which Sir Josiah pleads for the development of social shock absorbers and accommodating mechanisms to assist in the transition and to minimize the disturbances to social relations and institutions arising from the application of scientific discoveries, is immediately recalled by the third report* of the Commissioner for the Special Areas (England and Wales), which has now been presented to Parliament.

The Chancellor of the Exchequer, when introducing the Special Areas Bill to the House of Commons, aptly described it as an experiment—and, we may add, in view of the recent gift by Lord Nuffield of £2,000,000 to form a trust the activities of which will supplement the action of the State, an experiment which begins in the happiest circumstances The Act may in fact be interpreted as an endeavour to determine the value to the Special Areas of providing special treatment, and to ascertain whether the results thereby obtained warrant a wide application. As such, it may indeed be regarded as an example of the machinery of social change and adaptation which Sir Josiah Stamp had in mind.

In the present report, the Commissioner reviews the progress made since December 31, 1935, in the economic development and social improvement of the Special Areas. In many directions good progress has been made. An auspicious start has been made with trading estate companies for the north-east coast and for South Wales, and their activities should be favoured by the operations of the recently formed Special Areas Reconstruction Association. Evidence that financial assistance is required for small industrialists in the Areas is increasing, and the Commissioner considers that if the objectives of his recommendations are to be attained, somewhat greater risks must be taken in granting loans than are usually accepted by bankers and financial houses.

The formation of trading estates marks a direct and practical effort to attract industry, especially the lighter industries, to the Special Areas. Their expansion is essential to secure a better balanced industrial production, and the Commissioner reiterates the view expressed in his first report. He urges that efforts to attract such industries to the Areas should not be diminished on account of the prospective improvement arising from the defence programme on which Great Britain is now embarked. It is hoped that trading estates will become centres from which increased industrial activities will radiate.

Of specific works initiated, the most important is the construction of the deep-water quays near Jarrow, but the Land Settlement Association, the

Welsh Land Settlement Society and the Durham County Council are steadily progressing and the early results of these experiments in land settlement are regarded as satisfactory. They have demonstrated the adaptability and keenness of the settlers, whose general improvement in health and physique is remarkable. It is not generally realized how far below the standard strength and health of the ordinary active working man are those who have been long out of work, and how severely they suffer both physically and mentally from the loss of habit of work. A period of reconditioning is essential.

It is clear from the report that the Commissioner is far from satisfied with the results so far achieved, even if no more could be done with his comparatively limited powers. He repeats the criticism and recommendations of his first report, and especially stresses the importance of the Severn Bridge scheme as a gateway to South Wales, for which he was unable to make a grant. Similarly, to open up western Cumberland for industrial development and tourist traffic, he recommends the improvement of communications from the south and the construction of an arterial road, involving the construction of a bridge across the Duddon estuary. Improved communications between the north and south bank of the Tyne, east of Newcastle, are also recommended, as well as the institution of steps to prevent Maryport harbour from becoming closed and derelict.

Other specific recommendations in this field which have strong claims for State support are the erection of plants for the production of oil from coal in the Special Areas, the installation of a factory in South Wales for the manufacture of calcium carbide, and encouragement of the use of Welsh smokeless coal for domestic purposes. In the same category falls the proposal for the establishment and development on modern lines of a national park in South Wales. The development of the production of oil from coal in the Special Areas is recommended in the interests of national defence, and on the same grounds the Commissioner directs attention to the advantages of relative safety offered by some districts in South Wales and Cumberland in regard to the decentralization of the production of aircraft. For the same reason attention is directed to the value of South Wales, and West Cumberland as sites for the storage of grain and of oil.

The development and attraction of industry, however, is only one of the two main methods envisaged by the Commissioner for dealing with the problem of unemployment within these areas. Equal stress is laid upon the adoption of measures to decrease unemployment generally, thereby making easier a reduction of its intensity in the Special Areas. In dealing with this question the Commissioner again refuses to dissociate the particular problem of the Special Areas from that of unemployment generally. The effects of transference are being increasingly felt, and he reiterates his recommendation that an impartial and independent authority, with whom the trade unions should be associated, should conduct a survey to ascertain as scientifically and accurately as possible what are the relative prospects of industrial revival in the different districts of the Special Areas. Transference should be concentrated on these districts which obviously offer the least prospect of recovery.

Once again the Commissioner emphasizes the seriousness of the position in regard to unemployment among young persons. Pointing out that more than two thirds of the young men who were interviewed refused training at a Government constructional centre or failed to attend after acceptance, he reluctantly concludes that too large a number of young men in the Special Areas are content to live in idleness as State pensioners and are unwilling to make any effort to find work. The danger involved both to the young men themselves and to society as a whole leads the Commissioner to recommend, first that the proportion of men from the Special Areas who satisfactorily complete a course of training at the Ministry of Labour instructional centre should be greatly increased, and secondly, that such attendance on the part of young men from the Special Areas should no longer be on a voluntary basis but be subject to an approved measure of compulsion.

The scientific worker will be disappointed at finding among these specific recommendations no further reference to those suggestions regarding the application of science to industry which are being considered by the North East Development Board, although following the survey of the industrial facilities of the north-east coast published in April last, a technical advisory committee has been set up to provide for the further exploration of the economic potentialities of the Area. On the other hand, the further discussion of general principles contained in Part 1 of the report raises questions with which scientific workers are directly concerned. The very fact that the Commissioner, in restating principles previously outlined, finds it necessary to regret that they had not been recognized as a logical conclusion in debating his first report, indicates the need for closer attention to these questions.

As a means of increasing industrial activity in the areas, persuasion has definite limits and in fact is regarded as a failure by the Commissioner. On the other hand, compulsory location is regarded as unnecessary and dangerous ; the Commissioner finds an alternative in Government action to prohibit the location of industry in particular areas unless good cause can be shown His first recommendation is in fact that the further expansion of industry in Greater London should be controlled to secure a more evenly distributed production in which it is hoped the Special Areas would share.

The dangers attending the enormous post-War growth of Greater London, particularly in regard to adequate protection of food supplies in the event of a hostile attack, are cited in support of the Commissioner's argument that Government restraint on the further expansion of industry in the London area would indirectly benefit the Special Areas, and he refers to opportunities of exercising constraint at present available in the execution of the defence programme.

The Commissioner's recommendations involve the adoption of a definite plan to reduce unemployment in the Special Areas. He urges that if the Areas are to be given a reasonable chance of rehabilitation, industry must be attracted to them ; to start the movement the initial effort must be powerful. Moreover, although, as he repeatedly points out, the problems of the Special Areas cannot be dealt with entirely apart from the general problems and well-being of the nation, we must not be afraid of making a break with the traditions and practices of the past. The application of unconventional principles may well be called for, particularly in respect of preferential treatment, and the Commissioner's suggestion that the possibility of removing from the live register those who have been out of work for more than five years and are never likely again to obtain employment should be considered, deserves serious attention.

Once again, in fact, Mr. Stewart has made it apparent how closely this problem is linked up with that of rearmament, of health, education and industrial and social development generally. He firmly dismisses the idea that the defence programme offers any solution, and in fact directs attention to the dangers of armaments activity in the Special Areas if other measures are not simultaneously applied. Similarly, he directs attention to the dangers to health which are inherent in the conditions of the Special Areas, and his proposals for physical exercise and training as well as for instruction on relative food values, simple cooking and on the best way to distribute the portion of family income which is spent on foodstuffs, meet needs which are probably only more intense in the Special Areas but equally to be found elsewhere.

The scientific worker cannot but be impressed with the opportunity which many of the Commissioner's recommendations afford of gaining experience as to the value of numerous suggestions for social development which may well have a wide application if their efficiency is once proved. Action in this direction should not be thwarted by the opposition of vested interests, as is alleged by the Commissioner in regard to at least one of his earlier proposals repeated in the present report, and the attention which the report has already aroused in Parliament indicates that strong support for many of its recommendations should be forthcoming.

Undoubtedly the Commissioner's view of the position in the Special Areas is much less optimistic than that taken by Government spokesmen, and he is most emphatic on the need for definite action in accordance with widely developed and long-range plans. None the less, even when due account is taken of some tragedies of the Special Areas in regard to juvenile unemployment and disintegration of morale, the dominant impression created by the report is that of opportunity and hope. The task of rehabilitating and transforming these Areas and slowly reintegrating them into the national life is not insoluble. It makes big demands on vision and resourcefulness in planning, in research, and in redistribution of material sources and effort. Given the will and a vision of the social possibilities, success is assured, and the experiments may well prove of even greater value in the adaptation of national life as a whole to changed conditions. For this reason alone, apart from their incidental contribution in specific technical questions, the latest survey of the Special Areas claims the close attention of scientific workers as of other members of the community.

The Study of Mankind

L'Espèce humaine
Encyclopédie française, Tome 7. Pp. 574+40. (Paris: Comité de l'Encyclopédie française; Libr. Larousse, 1936.) 125 francs.

FOUR sumptuous volumes of this encyclopædic work have already appeared within a year under the general direction of Prof. Lucien Febvre. A total of twenty-one volumes is projected, including one of bibliography and one of indexes. The previous volumes are entitled "L'Etat Moderne", "Litteratures et Arts Contemporaines"; and the present one, "L'Espèce Humaine", is edited by Dr. Paul Rivet with the collaboration of M. Paul Lester and the aid of fourteen contributors. It has been issued in fifty-five fascicles, the complete quarto volume having a heavy black leather binding case.

The volume under notice is a discussion of anthropology in the widest sense, its three parts being devoted to (1) humanity to-day; (2) the question of peoples or races, including the notion of race, human palæontology, race crossing and the problem of classification; (3) population statistics and demography. Part I is richly illustrated with figures of human types and their activities, and begins with a historical discussion of what ethnology is. The various methods by which primitive implements were produced are described and illustrated in detail, as well as the uses of agglutinants, fibres, barks, fluids, etc. Other chapters are concerned with the social structure and supernatural beliefs of primitive peoples as well as their languages.

A chapter of twenty pages is devoted to the evolution of the idea of race, with illustrations from fossil skulls as well as from modern man. In another chapter, the biological phenomena of race are considered at length, and an attempt is made to introduce genetical conceptions. But although some French writers give Naudin credit equally with Mendel for the discovery of Mendelian inheritance, yet French investigators of heredity have always been few, and the bearing of genetical principles has not yet been widely grasped, especially in anthropology. In the present account the view still survives that mutations apply only to superficial characters, and that segregation in racial crosses frequently fails to occur, for example in negro-white crosses. The conception of duplicate factors and of linkage are conspicuous by their absence, the 15 : 1 ratio is regarded as contrary to Mendel's laws, and the significance of the numerous 1 : 1 ratios for a dominant abnormality crossed with the normal condition is not clearly stated. It is to be hoped that anthropologists will soon recognize more fully that genetical principles apply to man as extensively as they apply to animals and plants. In this connexion, the short account of the blood groups might have been greatly extended to indicate their racial significance.

The white Indians of San Blas are recognized as of mutational origin, but the author hastens to add that he uses the term in a very different sense from the geneticists. The latter, on the contrary, regard these Indians equally as an excellent example of mutation.

The chapter on fossil men contains many interesting views. The Australian aborigines are regarded as the most archaic of living peoples and are classified as belonging to the same species as Neanderthal man; but since the Australians cross with other modern peoples, it is suggested that Neanderthal and modern man must all be merged into one species—an extreme example of the application of the interfertility rule, which modern botanists and zoologists have dispensed with as a necessary criterion of species.

Aurignacian culture is regarded as represented by three races in Europe—Cro-Magnon, Grimaldi and Chancelade—which are all believed to have left modern descendants and to show affinities respectively with the white, black and yellow divisions of living man. A surviving Cro-Magnon type is seen not only in the Guanches on the Canary Islands but also in south-western France, especially the Dordogne, whence it may be traced across the Iberian peninsula. Similarly a modern Grimaldi type is recognized in various parts of northern Italy and the Rhone valley.

Two chapters on miscegenation are followed by a section on the problem of racial classification in which the views of Deniker and of Haddon receive fullest consideration.

Part III is a consideration of population and demographic questions from practically every point of view, including numerous statistics clearly set forth, with discussion of many problems relating to the present and past population of the earth.

The general reader, as well as the specialist, will find in this work ample material, whatever his special interest in man may be or whatever the point he wishes to elucidate. The abundant pages (72) of illustrations include several coloured plates.

R. RUGGLES GATES.

Structural Theory: Investigation and Rule

Final Report of the Steel Structures Research Committee
Department of Scientific and Industrial Research. Pp. xxvii+572+16 plates. (London: H.M. Stationery Office, 1936.) 12*s*. 6*d*. net.

BRITISH technical research has been, in the past, rather contemptuously treated by practitioners at home. The younger technicians have generally been carried away by the apparent profundity of Continental discussion, and the older industrialists have been only too happy to accept information of foreign origin without question. The same idea is displayed in the readiness to take up licences for developments elsewhere. This common and persistent attitude reflects a doubt as to the capacity of home efforts in inquiry and research to provide adequate guidance in design and development.

There may be reasons in some directions, but they can scarcely be held to apply in structural work. Several publications by the Department of Scientific and Industrial Research in recent years have shown that the powers of comprehension and compromise that properly constituted British committees can exercise are of the highest order. This was notably established by the Bridge Stress Committee Report in 1929; and has been maintained by the sequence of reports issued by the Steel Structures Research Committee, the final report of which concludes a line of investigation that is marked throughout by range, insight and decision. By describing this report as final, the Committee probably desires to indicate that it has concluded its work. There is, however, no finality in a study of this kind. Theory may be pursued to finer issues, investigation may lead to clearer data, and rules of design may reflect a fuller comprehension and a surer judgment; but the essential result is a compromise that denies finality since the theory and investigation are both, and separately, necessary and are drastically simplified in the process of rule making.

This final report presents rules for design, after lengthy study and experiment. The first report (1932) did very much the same thing after brief consideration and no experiment. The first report was an essay in creating order out of the chaos of building regulations. The final report is an effort to establish rules that rest upon rational bases elucidated by systematic inquiry. That the inquiry has upset preconceived notions as to the actions and interactions of the elements and connexions of building frames is an achievement of the Committee that may reduce the value of its own first attempt, but certainly leaves little merit in most other efforts.

The Bridge Stress Committee was almost wholly concerned with dynamic effects in bridge trusses. The Steel Structures Committee has concentrated almost entirely on static effects in building frames. The second report, issued in 1934, showed that in dealing with these, the problem of the characteristics of beam-stanchion connexions is complex and highly important. The work of the second report on this has been greatly extended. The honours in this line fall to Prof. C. Batho and his assistants, and the range and detail of the work now presented on the subject, embodying not only investigations on a wide variety of connexions and the factors influencing their actions, but also laboratory research on a full-scale frame, are remarkable for scope, experimental thoroughness and the manner in which design requirements are analysed. The investigations on bolted joints are strongly characterized by examinations of safe bolt torques, which make an important impression upon the ultimate issues of the report.

The other main experimental investigations presented in this voluminous report are concerned with measurement and analysis of stresses in actual structures. Prof. J. F. Baker and Dr. P. D. Holder are chiefly responsible, and the work marks new levels in large-scale research. Beam and column stresses in three classes of frames have been investigated. These frames are, respectively, for hotel, office and residential flat constructions, and mark the important continuation of the earlier work of this type by Dr. O. Faber on the framework of the Geological Museum, dealt with in the second report.

These measurements were undertaken to acquire information on the effects of workmanship under site conditions and to examine other factors that could, conceivably, influence stress distribution. The three types cover frame constructions with widely different connexion characteristics, the first having unusually rigid connexions, the second of normal order and the third of light construction. In the two latter the joint deformations were directly measured and, for the first, moment-angle diagrams are given as derived from the observed moments in beams and columns. The high degree of accuracy achieved is remarkable in view of the fact that testing was undertaken while actual construction was in progress. The discussion of the observations and the deductions therefrom are of great value. Such disturbing effects as beam torsion and the influence of unequal yields in the tension and compression cleats of connexions are duly commented upon; and the final review of the tests on the three buildings contains important remarks on the effects of casings and walls.

An analysis is presented of the effect of wind load moments, and attention is directed to the high values set up in the lower parts of the column when the stiffness ratio of beam to column is low. But the final recommendations for design only cover for stresses caused by vertical loads. It is to be accepted that in structures for which the design rules are used, the constructions must resist horizontal or wind forces by means of floor slabs and walls acting as bracing, or by special framing.

The design rules are presented with great clearness, and are the outcome of the rational lines of analysis developed in the various special studies on frames, stanchions and connexions. The rules are fully supported by tables and curves, and provide a relatively simple and straightforward procedure that is rather remarkable when the extraordinary range of data and detail study from which they emerge is viewed. In the structural trades, the rules will be the ready measure of the Committee's achievement; but to those who understand the technique of data accumulation, analysis and reduction in large-scale work, the labours that lie behind them, and lead to them, will be significant and highly impressive.

Foundations for Animal Painting

Animal Painting and Anatomy
By W. Frank Calderon. (The New Art Gallery, Second Series.) Pp. 336. (London: Seeley, Service and Co., Ltd., n.d.) 21*s.* net.

MR. CALDERON'S high reputation and the acknowledged influence he has exerted on the work of other distinguished animal painters guarantee that this new work from his hand will prove a trustworthy guide to the presentation of animal form in art. The first part of the manual is devoted to the general principles of picture-making and will repay perusal by the student of any branch of art, for here the author gives, from a ripe experience, much useful guidance in picture-making, combining a wealth of general principles with many useful hints about the handling of technical details—even to such minor points as the farm-hand with a switch who may be employed to prevent flies from disturbing the pose of a restive model! The second and much the larger part consists of detailed studies and descriptions of the anatomy of several animal types and the influence of anatomical detail on posture and surface form.

Both parts are profusely illustrated by pencil and charcoal drawings of admirable clarity, with the names of structures clearly indicated on the plates themselves—a method much to be preferred to numerical references, at the foot of the plates, so often to be found in manuals of this kind. Several useful reproductions of well-known pictures are added, to illustrate anatomical accuracy in observation or, in some instances, the absence thereof.

While the salient blood-vessels, which form such important features at many points in surface anatomy, are well described in the text, these are not so distinctly differentiated from the deeper structures in many of the plates; it would appear to have been worth while to have devoted some plates expressly to showing the prominent lines of these structures on the surface. With later editions in view, it should also be noted that in PL. 58 the skin-muscle is made to look like a bifurcation of the sterno-maxillaris instead of being shown on the more superficial plane to which it belongs. As one concerned to some extent in the correct delineation of human anatomy, the reviewer would also point to the unsatisfactory view of the shoulder girdle in PL. 63, the absence of the coraco-brachialis in PL. 124B and the exaggerated representation of the platysma in PL. 138.

These, however, are but minor points to cavil at in a work of supreme excellence, which is strongly recommended not only to the art student but also to all animal lovers, who will enjoy its *facile* and faithful drawings. No better advice could be given to any student, desirous of acquiring efficient technique in this branch of art, than that he should make careful copies of Mr. Calderon's plates on separate cards and then study those of anatomical detail in juxtaposition with those of surface form; it is certain that his own work will greatly profit in accuracy and natural semblance through the influence of these distinguished drawings.

ALEX. MACPHAIL.

The Excavation of Verulamium

Verulamium, a Belgic and two Roman Cities: By Dr. R. E. M. Wheeler and T. V. Wheeler. (Reports of the Research Committee of the Society of Antiquaries of London, No. 11.) Pp. xii+244+120 plates. (London: Society of Antiquaries, 1936.) 15*s*.

THE fame of the excavations at Verulamium, by St. Albans, has been widespread. They were visited by many thousands, and accounts were constantly disseminated by the lay Press, as well as by technical journals. Dr. and Mrs. Wheeler have done more than anyone else to create a great and genuine popular interest in the archæology of Great Britain. They have proved once and for all that English people do not need the enchantment of Egyptian or Mesopotamian distance to stimulate their enthusiasm for the unearthing of the past. Under the care of the Office of Works, and, in the case of the theatre, through the generosity of Lord Verulam, the remains of important buildings on the site are now permanently open to view, and the enlightened action of the St. Albans Corporation in initiating the whole enterprise will doubtless be maintained and extended in the future. The success of the work has been a fine example of co-operation between local and national authorities, private owners, archæologists, volunteer students, and the general public. Now the official report, worthily published by the Society of Antiquaries, is before us as the abiding record of the whole four years' campaign. It is no less an abiding reminder of the irreparable loss that we have sustained a few months since in Mrs. Wheeler's grievously premature death.

The very wording of the title, "A Belgic and Two Roman Cities", would have seemed almost impossible seven years ago. It had indeed long been guessed that the pre-Roman stronghold of the Belgic King Cassivellaunus, stormed by Julius Cæsar in 54 B.C., lay hereabouts, but its site had never been precisely localized. By their inspired refusal to rest content with exploring the later Roman Verulamium alone, Dr. and Mrs. Wheeler have not only identified and outlined the history of a pre-Roman town, but also have come as near as possible to giving Cassivellaunus' *oppidum* a well-certified location five miles away in the great earthworks at Wheathampstead. They have shown, too, that the earthwork known as the 'Fosse' is the rampart of an early Roman Verulamium, in great part distinct from the recognized site of the later Roman city.

The historical sequence thus revealed is broadly speaking as follows: In the decades before Cæsar's invasions, Belgic conquerors from northern Gaul appeared in the Hertfordshire district, establishing their greatest stronghold at Wheathampstead, and fortifying their north-west frontier with the immense barrier of the Beech Bottom Dyke between the Rivers Lea and Ver. Forty years or more after Cæsar had come and gone, the first Verulamium came into being on the Prae Wood hill above the ford of the Ver opposite the Beech Bottom alignment. Here King Tasciovanus, the father of the greater Cunobeline, had his capital and mint.

After the Roman Conquest of A.D. 43, this site was abandoned, and the early Roman city was settled on the slopes below leading down to the all-important ford; through it ran the Imperial road from London to Chester, our Watling Street. This *municipium* was still without defences when it was sacked by Queen Boudicca's rebels in A.D. 61, but when restored thereafter it was furnished with the rectilinear defensive 'Fosse'.

In the second century, a further downhill move was made, and a new Roman city was laid out on an ambitious scale along the Watling Street beside the river, and dignified with the massive masonry-faced ramparts and deep ditches in part still to be seen. These tremendous walls, their towers and gates, two triumphal arches, a forum, shops, temples, a theatre unique in Britain, and many comfortable private houses, all attest "an age of colonial enterprise" when "the dignity of a distinguished provincial municipality demanded expression", and furthermore, "reflect an epoch when imperial and private speculators were investing their wealth in the British province to an extent which, in fact, the issue failed utterly to justify". A hundred years later, all was in decay, and the revival which under Constantius ushered in the fourth century was indeed accompanied by much rebuilding, but ended with that century in the shrunken decline of economic failure.

For the pre-Roman phases, this historical framework is mainly based on mutually helpful studies of fortifications and of pottery, though the excavations could not be extended over much of the actual areas of settlement. This handicap is graver in the case of the first Roman city, where the confident handling of the evidence from the defensive 'Fosse' makes one almost forget that the interior remains absolutely unknown. With the second Roman city the position is in a measure reversed:

from inside it, information is abundant, but the walls, towers, and gates have not been too generous of material, and their chronology has required some rather anxious argument from negative evidence.

The built-up areas within have provided the most uniformly successful sections of the report; probably no excavation on a Romano-British town site has ever been more laborious yet more superbly conducted and brilliantly described. It is impossible to go into detail here, but the section on the 'Triangular' temple demands especial mention, while the peculiarly interesting theatre has called for publication at greater length in *Archæologia* by its excavator, Miss Kathleen Kenyon. The plans and drawings, mostly by Dr. Wheeler himself and Mr. A. W. G. Lowther, are everywhere splendid, and the coloured reproductions of the mosaic pavements by Mrs. Wheeler and others are as beautiful as their text is illuminating.

To historians, and especially economic historians, this work should above all be commended; the archæological method is now an essential instrument of their science, and seldom can a single excavation report have carried so much matter for thought so far beyond the circle of archæological specialists. C. F C. HAWKES.

Illustrations of Weeds

Weed Plates

By Prof. Dr. E. Korsmo. Series 2, Plates 31–60: Comprising 44 Species of Weeds on Cultivated Soil. 33in. × 25in. With explanatory Booklet of 92 pp. (Oslo: Norsk Hydro-Elektrisk Kvaelstofaktieselskab; Leipzig: Koehler und Volckmar A.-G. und Co., 1935.) Paper, 22 gold marks; Leather paper, cloth edges, eyeletted, 38 gold marks.

THIS second series of illustrations of farm weeds fully maintains the high standard of execution and reproduction of the preliminary set (see NATURE, 135, 937; 1935). The presentation of each weed provides an education in its life-history and in many cases demonstrates in a most striking manner why any particular species is peculiarly difficult to eradicate.

The plates reveal the variety of methods of reproduction of individual weeds, many of which are frequently overlooked by the trained botanist as well as by the casual observer. For example, *Ranunculus ficaria* produces seed, bulblets in the leaf axils, and 'root tubers', all capable of withstanding a variety of adverse conditions and thus insuring the safety of the species. The great range of subterranean systems of weeds often remains unsuspected, as the aerial parts give little hint of what is happening below ground. The variety of morphological development in this direction may be indicated by *Mentha arvensis*, which possesses an amazing underground range of tubers, *Campanula rapunculoides* which forms an extensive creeping underground system with storage roots, *Bunias orientalis*, a crucifer with an exceptionally deep root and great basal leaves which may be two feet long, while *Polygonum bistorta* gains its name of 'snakeweed' from its fantastically twisted and curved rhizome.

A valuable feature of the illustrations is the help they give in distinguishing closely allied species, such as *Bromus secalinus* and *Bromus mollis*. For teaching purposes, also, many details are brought out which usually escape observation. Most students regard a poppy capsule as a partitioned box filled with numerous loose seeds, as it actually is when ripe, while the systematic attachment of the young seeds on the walls of the loculi is seldom realized. Another point is the wide range of variation in the size of the fruit of such species as *Atriplex patula*, which at first sight appears accidental, but is in reality a feature of the species. Yet again, special notice is taken of characteristic forms of hairs, which are often valuable aids in the determination of species, as the stellate hairs found in *Berteroa* (*Alyssum*) *incana*. Examples of this kind might be multiplied indefinitely, all pointing to the expert knowledge of teaching requirements which inspired the preparation of the plates.

Throughout the series, each weed is recognized as an individual, and no stereotyped form of treatment has been attempted. In each case the particular points of interest have been worked out, and the development of a single detail is often illustrated by a whole series of drawings. Of special value are the sketches of the early stages of such weeds as *Galeopsis*, which are not usually at all well known by botanist or student.

A third series of plates is due to appear, and on their publication the botanical world will be in possession of a work on the morphological details of farm weeds which is outstanding in the accuracy of its workmanship. These charts, together with Prof. Korsmo's recent book on weed seeds, with its beautiful coloured illustrations and detailed letterpress, will undoubtedly become a classical work of reference for many generations to come.

Sex

By Dr. B. P. Wiesner. (Home University Library of Modern Knowledge, No. 180.) Pp. 256. (London: Thornton Butterworth, Ltd., 1936.) 2*s*. 6*d*. net.

It is not surprising to find that this book departs in some ways from the tradition set by others on scientific subjects in this well-known series. In the first place, the subject itself is not restricted by the formal confines of academic curricula, and Dr. Wiesner has had to draw on such diverse branches of knowledge as physiology, anatomy, endocrinology, genetics, general biology and psychology. In so doing, the author has revealed a second feature of his departure from Home University Library orthodoxy, by showing himself an original thinker and by asking the lay reader to consider hypotheses, to weigh evidence and, in short, to puzzle things out for himself, instead of merely accepting *ex cathedra* statements about scientifically established 'facts'.

The nature of Dr. Wiesner's subject has doubtless in part dictated his technique of exposition, but a reading of this concise survey suggests that temperamental influences may also have played their part. However that may be, he has produced a book that is packed with information and interest; this may make it less easy reading for the layman than the conventional popular exposition of a technical subject, but will give it a special appeal to the scientific worker.

Apart from a few minor oversights in typography and phraseology, the actual presentation of Dr. Wiesner's matter calls for little criticism, for it lacks neither clearness nor elegance—if, indeed, any distinction whatever is to be made between the two. The drawings and diagrams add to the general lucidity of exposition. To the technician, the most controversial, and therefore the most attractive, part of the book will probably be the discussions on the relation between sexuality and reproduction (especially Chapter v) and on the evolution of sexuality.

A. L. B.

Tables annuelles de constantes et données numériques de chimie, physique, biologie et technologie

(Annual Tables of Constants and Numerical Data; Chemical, Physical, Biological and Technological). Données numériques sur le pouvoir rotatoire (Numerical Data on Rotatory Power). Par Prof. E. Darmois. Années 1931 à 1934. Pp. 68. (Paris: Gauthier-Villars; New York: McGraw-Hill Book Co., Inc., 1936.)

This is a collection of data obtained on optical rotatory power between 1931 and 1934, and is an advance paper from vol. 11 of the well-known "Tables annuelles". The matter is grouped in seven sections: specific rotatory powers; influence of temperature, concentration and solvent; rotatory dispersion; resolution of racemic compounds; mutarotation; effect of additions; and general theories. Of these the largest section is that on rotatory dispersion, which occupies more than half the volume. Among the interesting results recorded in this section one may note in passing the work of Lowry and Gore on the vapour of camphor and camphorquinone, and that of Levene on a number of aliphatic compounds in which the rotatory dispersion is followed through an absorption band. Section 4 includes a number of resolutions of theoretical interest such as Mann's purely inorganic compound $Na[Rh(SO_2N_2H_2)_2(H_2O)_2]$, and on the organic side Pope and Whitworth's resolution of *spiro*-5 : 5-dihydantoin and Backer and Schurink's work on *spiro*-heptane dicarboxylic acid.

The numerous workers in the field of optical activity will be grateful to Prof. Darmois for this valuable summary of recent work.

Technische Kunstgriffe bei physikalischen Untersuchungen

Von Prof. Dr. Ernst von Angerer. (Sammlung Vieweg: Tagesfragen aus den Gebieten der Naturwissenschaften und der Technik, Heft 71.) Dritte Auflage. Pp. ix+201. (Braunschweig: Friedr. Vieweg und Sohn, 1936.) 9.80 gold marks.

Prof. von Angerer was entrusted with the preparation of the volume on experimental technique for the Wien-Harms "Handbuch der Experimentalphysik", and the present publication represents the third edition of his "Kunstgriffe", so that it must from the outset command attention. Indeed, it is a most interesting little book in which every experimenter is bound to find something which will appeal to him personally.

It is obvious that the author has taken considerable pains to keep himself thoroughly up to date with modern advances in laboratory arts and technique, and it is clear, too, that in many instances he has tested them for himself. Omissions, so far as the reviewer has been able to judge, are very few, although it is surprising that no mention is made of Hulett's method of purifying mercury, and also to find that two constant-temperature baths instead of three are shown in thermo-couple diagrams. However, such details detract but little from the excellence of the work as a whole, and it can be heartily commended.

L. F. B.

Experimentelle Grundlagen der Wellenmechanik

Von Dr. S. Flügge und Dr. A. Krebs. (Wissenschaftliche Forschungsberichte: Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 38.) Pp. x+236. (Dresden und Leipzig: Theodor Steinkopff, 1936.) 16 gold marks.

The collaboration of a theoretical physicist with a colleague who is an experimenter naturally results in a book of wide appeal, even if both authors feel it necessary to deal with many important branches of modern physics in a small space. It provides a ready guide for readers who wish to know the present state of wave mechanics theory, its experimental basis, and how far the theory is able to provide new and more adequate explanations for the results of fundamental experiments. It is an interesting compilation. The reviewer, however, would scarcely term Schopper's experiment for the direct measurement of e, a method for finding e/m.

The Oxford University Arctic Expedition, 1935-36

By A. R. Glen

THE plans of the Oxford University Arctic Expedition, 1935–36, were briefly outlined in an article which appeared in NATURE of April 20, 1935, p. 604. The Expedition returned to England in September last after a stay of fourteen months in the barren North-East Land. The country, which is somewhat larger than Wales, has the greater part of its interior covered by ice cap; its coasts are broken up by many deep fjords which are divided one from the other by rocky promontories from which the ice covering has long since disappeared. The north coast, which fringes the Polar Ocean, was practically unknown, while there was also little knowledge of the east coast, which is made up of an almost continuous stretch of ice cliffs—these being the largest expanse outside the Antarctic.

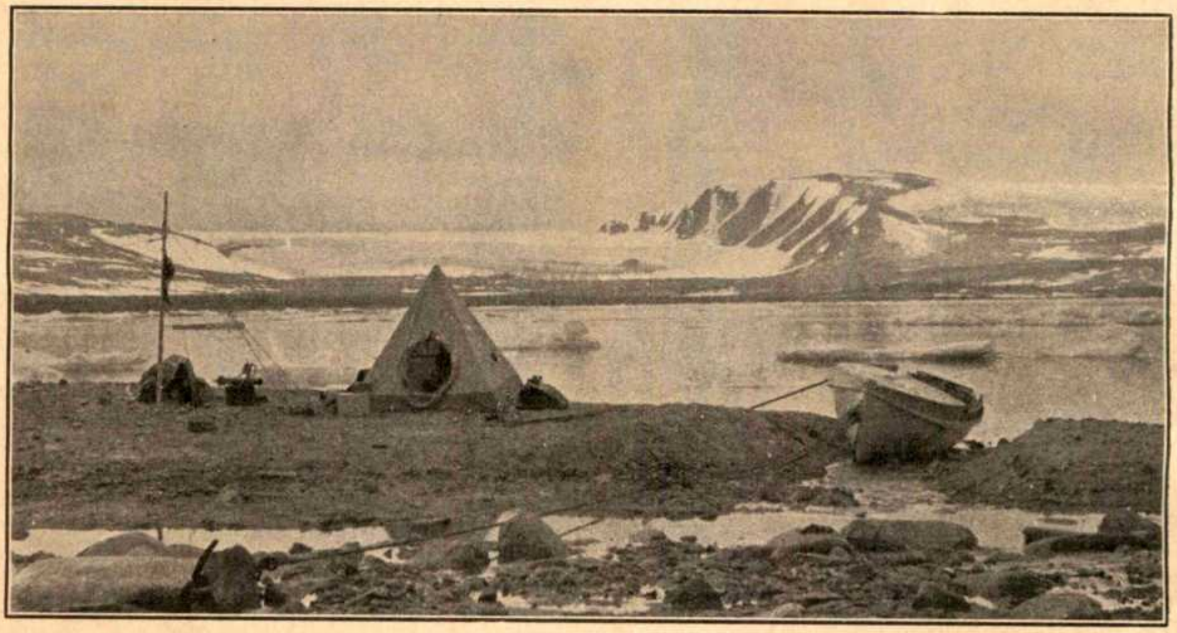

Fig. 1.
A CAMP ON THE NORTH COAST OF NORTH-EAST LAND DURING THE BOAT SURVEY JOURNEY IN THE FIRST SUMMER.

The personnel of the Expedition consisted of ten members who were as follows: A. R. Glen (leader and glaciologist), N. A. C. Croft (photographer), A. Dunlop Mackenzie (organizer), J. W. Wright (surveyor), A. S. T. Godfrey (surveyor), R. M. Moss (physicist), R. A. Hamilton (physicist), A. B. Whatman (in charge of radio research), D. B. Keith (biologist), K. J. Bengtssen (trapper).

The biological work of the Expedition will be dealt with in another article. For the remainder of the research, it may first be said that the whole programme of the Expedition was successfully achieved. Climatic conditions did nothing to facilitate this, for although the temperature never fell so low as had been anticipated nor were the gales so severe as had been feared, yet prevailing blizzard and predominant fog much complicated survey and geological investigations. During the summer of 1935, the western part of the north coast was surveyed in the course of a boat journey made by Wright, Keith and Bengtssen. The polar ice retreats from the coast during the summer, allowing the use of small boats until the bays begin to freeze again in September, and this party only returned to the base before the autumn gales began. In the following spring, Wright and Mackenzie started off with a dog team to sledge along the eastern part of the north coast so as to complete the survey and if possible to continue it down the east coast. In the previous autumn and winter, journeys had been made in the darkness to lay depots at three strategic points, Cape Leigh Smith, Palander Bay and Wahlenberg Bay, which should be used by this spring survey party. What had not been allowed for, however, was the weather; continuous fog and low cloud made survey quite out of the question except on one or two days during each month. The result was that by the time the bay ice was beginning to break up in early July, a considerable part of the north coast still remained to be mapped. Wright and Mackenzie therefore returned to the base in Brandy Bay after a narrow escape from disaster when crossing Rijps Bay in an improvised boat. A second party was quickly fitted out, and a few days later Wright and Hamilton set off for Cape Leigh Smith, which they reached after nine days hard travelling. The weather suddenly became good, and in a fortnight's work the mapping of the north coast was completed (Fig. 1). The greater part of the survey of the rest of the country was also carried out by other sledge parties, and North-East Land must now be considered as one of the best mapped countries in the Arctic.

The main problem of the geological investigations was in connexion with the relation between the Hecla Hoek rocks and the granites and gneisses which are found around North Cape and also form the eastern part of the north coast. The eastern arcs of the Caledonian folding have affected this region, and although the absence of a full-time geologist greatly hindered this work, a considerable amount of research was carried out on these problems. The geological structure of the western part of the north coast was mapped in detail and some interesting discoveries were made in the little metamorphosed rocks of the younger Hecla Hoek series.

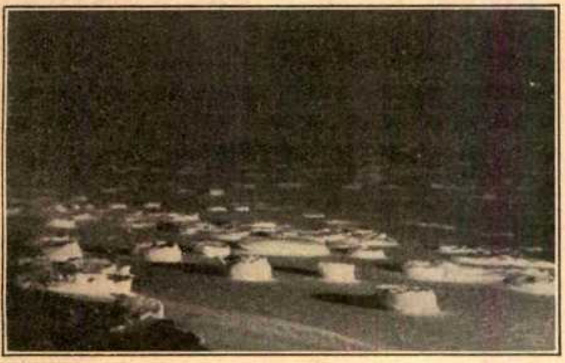

Fig. 2.
RAISED FOOTSTEPS ON THE SNOW SURFACE DURING THE WINTER. FOOTSTEPS ARE PACKED DOWN AND THE SOFTER SURROUNDING SNOW IS REMOVED BY WINDS, LEAVING THE FOOTSTEPS RAISED ABOVE THE REST OF THE SURFACE. TAKEN AT MIDDAY IN DECEMBER AT THE NORTHERN ICE CAP STATION DURING THE FOUR MONTHS WINTER DARKNESS.

Perhaps the most interesting work of the Expedition was in connexion with the glaciological investigations. In order to carry these out, it was planned to establish two stations on the inland ice, each of which should be maintained by two men over the winter. The only previous work of this nature was accomplished by the German expedition under the late Alfred Wegener, when their station Eismitte was set up in the centre of the Greenland ice cap. Difficulties of transport resulted in only the barest minimum of food and equipment being brought to Eismitte, and in appalling circumstances the Germans succeeded in producing a wonderful harvest of scientific results. Our problem was simpler in so far as distances were shorter, and we had the guidance of previous experience; but there were the same difficulties to be overcome in the way of blizzards and low temperatures, while four months darkness was a further complication. A solution was found in having the stations cut out of the ice, and amazing warmth and comfort was attained in this troglyditic existence. Moss was in charge of the central station for ten months, during three of which he was alone, while Glen and Dunlop Mackenzie formed a wintering party at the northern station (Fig. 2). Meteorological investigations were taken

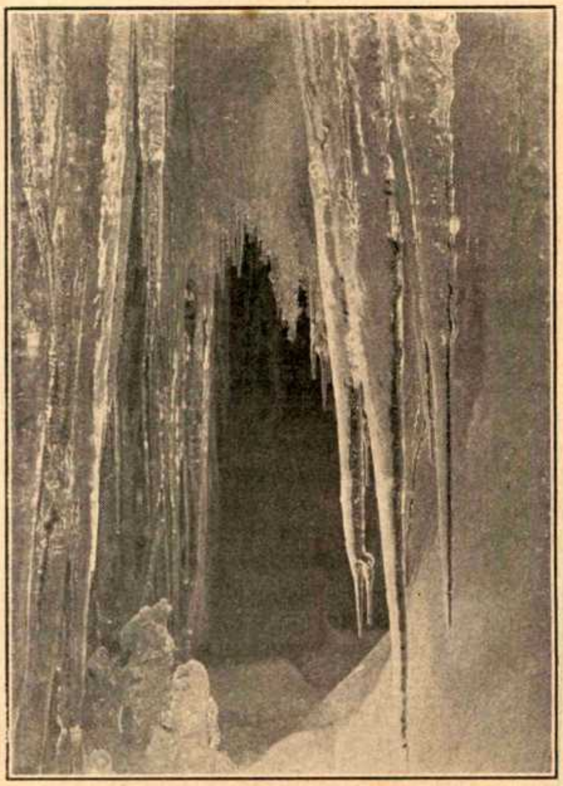

Fig. 3.
CREVASSE DISCOVERED AT THE CENTRAL ICE CAP STATION WHILE A SHAFT WAS BEING DUG TO 40 FT. BELOW THE SURFACE. A DEPTH OF 70 FT. WAS REACHED IN THE CREVASSE, BEING ONLY A FEW FEET FROM THE LAND BELOW.

three times daily at each station at the same hours as at the base, whence results were sent by wireless after each reading to Norway.

The net balance of the ice cap—that is to say, the ratio between the factors of accumulation and ablation—was determined for the west ice over the year, and preliminary discussion of the results obtained indicate that the northern part of the ice cap is probably both shrinking and retreating. The different factors obtaining both in accumulation and ablation were separately measured and their relative proportions assessed, while research was also made on various physical questions connected with the ice itself and with the change of snow into ice. The temperature gradient was measured down to a considerable depth, and it was found at the central station that the temperature remained at a fairly constant 0·0° C. at a depth of 70 ft. Certain indications of the thickness of the ice were obtained indicating that at least the west ice is very much thinner than had been thought. A crevasse was discovered while digging a shaft at the central station, and through it we were able to penetrate to a depth of more than 70 ft., where an unfrozen ice lake was found (Fig. 3). The walls of the crevasse were covered with a glittering array of ice crystals while magnificent icicles across the passages formed curtains which had to be cut down before a way could be found along them (see also NATURE, Nov. 7, p. 803).

At the base in Brandy Bay, Whatman and Hamilton were stationed practically continuously throughout the whole expedition. They were in charge of the important research on the ionosphere which was being carried out for the first time north of the auroral belt. Before departure from England, it had been feared that the severe climatic conditions would make it impossible successfully to accomplish this work, but so efficient was the whole apparatus and the Petter electrical generating unit, that not a single serious breakdown occurred over the entire year. The results are now being examined by investigators at the Radio Research Station at Slough, in co-operation with which, and also with the Norwegian Government Station at Tromsö, the records were taken. Special studies were also made of the aurora, and measurements were made of the atmospheric ozone.

By the end of August the scientific programme had been accomplished and the M.S. *Heimland* arrived in Brandy Bay on August 21. The base hut has been bought by the Norwegian Government, and after it had been inspected and the stores and equipment loaded on to the ship, we left Brandy Bay on the following evening.

Scientific Centenaries in 1937

By Eng.-Capt. Edgar C. Smith, O.B.E., R.N.

WHEN reference was made in these columns a year ago to the scientific centenaries in 1936, the first man of science to be recalled to mind was the famous German mathematician Johann Müller, or Regiomontanus, who was born in 1436. In reviewing the centenaries which will fall this year the first name to be included is that of Christopher Clavius (1537–1612) whose birth occurred a century later. Born at Bamberg, in Germany, he entered the Society of Jesus, taught for many years in Rome—earning for himself the appellation of "the Euclid of the 16th Century"—was employed by Pope Gregory XIII on the reformation of the calendar, and in 1604 published his most important book, "Geometria Practica". He died February 6, 1612. Another mathematical worthy of the sixteenth and seventeenth centuries was Henry Gellibrand, who was born in London in 1597 and died as Gresham professor of astronomy in February 1636 (O.S.) or 1637 (N.S.). It was Sir Henry Savile who turned Gellibrand's attention to mathematics, and at the Gresham College he became the close friend of Henry Briggs.

> "Mr. Gellibrand's situation at the College, free Converse with the Lovers of Mathematical Studies, and diligent Enquiries, gave him," wrote Benjamin Martin, "an Opportunity of contributing much to the Improvement of Navigation, which probably would have owed more to him had he lived longer: But he was taken off February 9, 1636, in the 40th Year of his Life, and was buried in the Church of St. Peter the Poor, without any Inscription to his Memory".

The year 1637 also saw the birth of another English mathematician who had but a short life, William Neile, who died at the age of thirty-four years. He had been elected a member of the Council of the Royal Society at the age of thirty, and according to the antiquary Hearne, his powerful genius for mathematical studies was such "that had he not been cut off in the prime of his years in all probability he would have equalled, if not excelled, the celebrated men of that profession".

Whatever interest is to be found in the lives of Clavius, Gellibrand and Neile, however, is far surpassed by that which surrounds the activities and strange ending of the great Dutch naturalist Jan Swammerdam (1637–80). He imbibed a love of natural history from his father, and was trained for medicine. He became famous both as an anatomist and as a microscopist.

> "Swammerdam," said Prof. Miall, "treated the microscope as an instrument of continuous biological research. In his eyes it was a sacred duty to explore with the utmost faithfulness the minute works of the Creator. Insects yielded him an inexhaustible supply of natural contrivances, in which closer scrutiny always brought to view still more exquisite adaptations to the conditions of life. He was able to throw a beam of steady light upon the perplexed questions of insect-transformation, and swept from his path the sophistries with which the philosophy of the schools had obscured the change of the caterpillar into a moth, or of the tadpole into a frog. . . . He bequeathed to his successors many noble examples of the way in which life-histories ought to be investigated."

About 1672, Swammerdam came under the influence of that strange religious visionary, Antoinette Bourignon, and, already of feeble constitution, he slowly sank into an early grave through overwork and the melancholy engendered by mysticism. Under the pressure of indigence he had sold many of his writings and drawings. These came into the possession half a century later of Boerhaave, who caused them to be published under the title "Biblia Naturæ", in 1737.

Passing from the men of science who laboured in the seventeenth century to those who belong to the eighteenth century, the outstanding name is that of Aloisio Galvani, the bicentenary of whose birth falls on September 9. Born at Bologna, he was educated, and practised and lectured there, and it was there he made his discoveries on animal electricity which his countryman Volta referred to as "a great and luminous discovery which forms an epoch in the annals of physical and medical science". His death took place in 1798; the centenary of which event was marked by suitable ceremony at Bologna. Of other men born in 1737, mention may be made of Dr. Richard Watson (1737–1816), Bishop of Llandaff, who lectured at Cambridge on chemistry; Guyton de Morveau (1737–1816), whose career is noticed in another column (p. 18); Jean-Nicolas Ceré (1737–1810), who as director of the Royal Botanical Garden at Mauritius earned the gratitude of European naturalists by his gifts of plants; Alexander Dalrymple (1737–1808) who, in his early days a writer in the East India Company's service, rose to be hydrographer to both the East India Company and the Admiralty; William Bayly (1737–1810), the astronomer who accompanied Cook on some of his voyages; William Forsyth (1737–1804), the Scottish horticulturist, whose name is recalled by one of our most beautiful of early flowering shrubs; Colonel H. Watson (1737–86), who translated Euler's work on the construction and manœuvring of ships and practised naval architecture with great success; and Dr. Charles Hutton (1737–1823). Hutton began life with few advantages, but by unremitting labour gained for himself a prominent place among British mathematicians. For thirty years he was a professor at the Royal Military Academy, Woolwich, and in 1779 he became the foreign secretary to the Royal Society. He was editor of the *Ladies' Diary*, made the calculations in connexion with Maskelyne's experiments on the density of the earth, carried out experiments on gunnery, and in 1795 published a valuable mathematical and philosophical dictionary.

Of those whose lives began in the eighteenth century but who died a hundred years ago, the one with, perhaps, the highest reputation was Karl Ernst Adolf von Hoff (1771–1837), the German geologist to whom a tribute was paid in NATURE for June 8, 1905. "Von Hoff's position as an original thinker," it has been said, "is at least equal to that of Lyell." A diplomatist and immersed in the international confusion of the Napoleonic era, he yet found time to establish a geological journal in 1801 and carried on those studies which led to the writing of his great work, "The History of the Changes in the Surface of the Earth". Other men of science who died in 1837 include Edward Turner (1798–1837), professor of chemistry in University College, London, who did important work on the atomic weights of the elements; William Ritchie (1790–1837), a student under Gay Lussac and Biot, who in 1829 became professor of natural philosophy at the Royal Institution; Domenico Scina (1765–1837), a learned Sicilian physicist who became chancellor of the University of Palermo; Martin van Marum (1750–1837), a Dutch physicist who made many electrical experiments and was secretary to the scientific society of Haarlem; and John Latham (1740–1837), the ornithologist, who at eighty years of age began his "General History of Birds" (1821–28). To engineers the name of Arthur Woolf (1766–1837) recalls many important improvements in the steam engine, while that of Claude-Pierre

Molard (1758–1837) will always be associated with the foundation in Paris of the Conservatoire des Arts et Métiers. Early in his career, Molard was brought into contact with Vaucanson, and was placed in charge of the collection of models which Vaucanson gave to France. It was only natural that when the Government, on the report of the Abbé Grégoire, decided to found the Conservatoire, Molard should be appointed its first director. When elected to the Paris Academy of Sciences, Molard was given the seat vacated by Napoleon.

During the last hundred years, through various causes science has engrossed the attention of so many workers that the list of men eminent for one reason or another who were born in 1837, a century ago, is a long one. The list given below does not claim to be complete, but the notes given will suffice to recall some of the activities of the nineteenth century. Among the ranks of the physicists, Eleuthere Elie Nicolas Mascart (1837–1908) was certainly one of the most widely known scientific men of his day. As successor to Regnault at the Collège de France, as director of the Central Bureau of Meteorology in Paris, and as president of the Paris Academy of Sciences, he rendered notable service to science in France, while as president of various international gatherings he had a wide reputation as an organizer. He died on August 26, 1908, and was buried with military honours in the cemetery of Montparnasse, in which rest the remains of Regnault, Biot, Foucault, Dumas and Ampère. Another eminent French physicist born in 1837 was Emile Sarrau (1837–1904), a professor in the Ecole Polytechnique and for many years director of the laboratory of the Ecole des Poudres et Salpêtres. He wrote on light, heat, gases and ballistics, and was a collaborator with Berthelot on investigations on explosives. The year 1837 also saw the birth of the German meteorologist Wilhelm von Bezold (1837–1907), director of the Meteorological Institute in Berlin; of Admiral Carl Koldeway (1837–1908), the commander of two arctic expeditions and an authority on magnetism; of Johann Diderik van der Waals (1837–1923), the eminent Dutch physicist; and of the Belgian Jesuit Eugène Lafont (1837–1908), a pioneer in scientific education in India. Sent to St. Xavier's College, Calcutta, in 1865, Lafont erected a meteorological and astronomical observatory and a physical laboratory, and afterwards took an active part in the work of the University of Calcutta, and was a founder of the Indian Association for the Cultivation of Science.

What Lafont did for physics in India, Edward Divers (1837–1912) did for chemistry in Japan. In 1873, at the invitation of the Public Works Department of that country, he with ten other Englishmen went to Tokyo to found a college of engineering. For twenty-six years he laboured there, and to-day a bronze statue of him stands in one of the courtyards of the Imperial University. In 1905–6 he was president of the Society of Chemical Industry. The chemist, John Alexander Reina Newlands (1837–98), was also born a hundred years ago. As a young man of twenty-three years of age he fought under Garibaldi for Italian freedom, and it was soon after his return home and while practising as an analytical chemist in London, that he sent a letter to the *Chemical News* containing his earliest views on periodicity among the chemical elements; views which were regarded at first as fantastic but which afterwards gained for him the Davy Medal of the Royal Society.

The ranks of astronomers have ever been recruited from many sources, some of the most eminent workers in this science beginning their careers in circumstances which were little likely to lead them to the computing room and the observatory. This is exemplified by the lives of several men whose centenaries fall this year. Richard Antony Proctor (1837–88), one of the most popular lecturers and writers on astronomy, and one of the keenest observers, began life as a bank clerk in London; Ralph Copeland (1837–1905), who was Astronomer Royal for Scotland in 1889–1905, spent his early years on the sheep-runs and amid the gold diggings of Australia, while Frank McClean (1837–1904), as well known for his generous gifts to astronomy as for his own work on the spectra of the stars, was originally a civil engineer. William Harkness (1837–1903), too, who was born at Ecclefechan, Scotland, and who became director of the Naval Observatory at Washington, was a medical man before he became an astronomer, while his American contemporary Henry Draper (1837–82), in whose honour the United States Government struck a transit of Venus medal, was a professor of physiology. On the other hand, Edmund Weiss (1837–1917), assistant and successor of Littrow at the Vienna Observatory, began life as an astronomer. Another name of interest in connexion with these centenaries of astronomers is that of the American financier Charles Tyson Yerkes (1837–1905), who, with funds accumulated through his railway enterprises in Chicago, founded the Yerkes Observatory of the University of Chicago.

In conclusion, passing reference may be made to a few men distinguished for their work in various other branches of science or industry whose centenaries fall this year. Henry Hicks (1837–99), the president of the Geological Society in 1896–98, was a surgeon by profession, and it was his contact with J. W. Salter which made him a devoted student of geology and palæontology; Raphael Pumpelly (1837–1923) turned geologist on coming under the influence of Noeggerath at Freiburg, and so embraced a profession which brought him a life full of adventure in many lands, while Thomas Davies (1837–93), who edited the *Mineralogical Magazine*, followed in the footsteps of his father William Davies (1814–91) when in 1858 he entered the service of the British Museum. Among metallurgists, few in his day were known better than George James Snelus (1837–1906), who for his work on the elimination of phosphorus from molten pig iron, received in 1883 one Bessemer Gold Medal, while another was given to Sidney Thomas. In Germany, no man did more to establish the engineering industry on a sound basis than Ludwig Loewe (1837–86), the founder of a still famous firm, while American invention and engineering are recalled by the names of Robert McAlpine (1837–1911), a pioneer in the manufacture of paper from ground wood pulp, and Colonel Washington Augustus Roebling (1837–1926), to whom fell the task of constructing the Brooklyn Bridge at New York.

The Iguanodons in the Brussels Museum

WE are glad to record that the unique collection of skeletons of the Wealden dinosaur *Iguanodon* in the Royal Museum of Natural History at Brussels has now been installed for safe preservation in two air-tight glass cases, which are probably the largest exhibition cases hitherto placed in a museum. The twelve skeletons, which are mounted in their natural position on iron framework, occupy a case which measures 18 metres in length, 11 metres in maximum width, and 7 metres in height. Part of it is shown in the accompanying photograph (Fig. 1). The skeletons which still lie attached to masses of rock are covered with a case measuring 20·5 metres in length, 13 metres in width, and 7 metres in height. The cases were made by the Belgian branch of the English firm, Messrs. Fred. Sage and Co. Ltd., which has supplied cases to the British Museum and to other English museums.

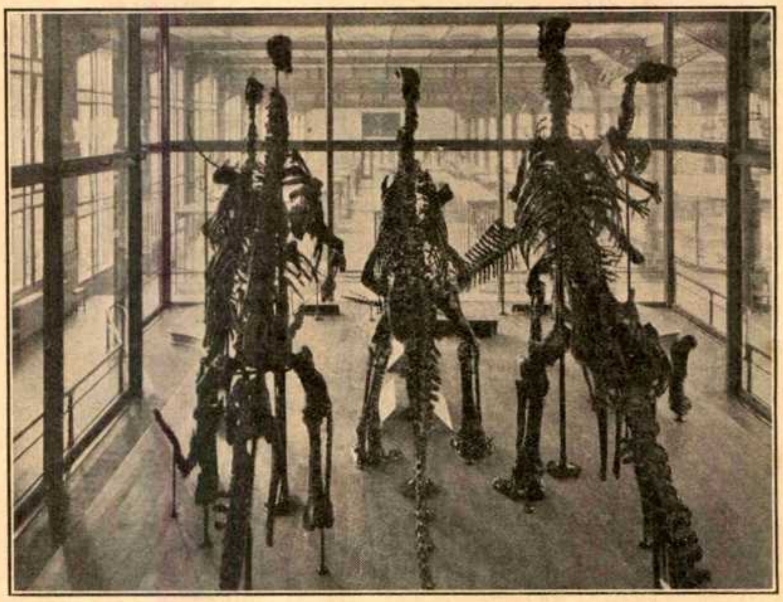

Fig. 1.
IGUANODONS IN THE ROYAL MUSEUM OF NATURAL HISTORY, BRUSSELS.
Photo by E. Sergysels, Brux.

When these fossil bones were first extracted from the rock and prepared for study between 1878 and 1900, they were hardened with an aqueous solution of gelatine. The treatment, however, proved to be insufficient to prevent the decay of the iron pyrites with which most of the specimens were permeated, and a few years ago it became evident that the collection could only be preserved by some other method of hardening the bones and by protecting them in future from contact with more or less damp air.

To devise a new treatment was difficult, because much of the gelatine still remained in the fossils and prevented the absorption of any other material. Experiments were therefore made, and it was decided to remove the gelatine so far as possible and replace it with shellac to be deposited from a solution in alcohol. The bones were washed with tepid soapy water to which a little carbonate of soda had been added, and after each washing they were rinsed with tepid water and carefully dried in a heated chamber. Immediately after drying, and while still at a temperature of 45° C., they were placed for twenty-four hours or more, according to size, in a bath containing shellac dissolved in alcohol, one part of shellac to three parts of alcohol at 94° C. When the bones were taken out of the bath they were washed with alcohol to remove the excess of shellac, and then they were left to dry in a current of air at the ordinary temperature while the solution completely impregnated them. The process was repeated once, and the bones were then ready for the preparators, who mended cracks and other deficiencies. Finally, a weaker solution of shellac, one part to four parts of alcohol, was driven by a compressed-air syringe into the surface of the bones, and they were again left to dry. This process was repeated three times, and the specimens were then re-mounted on their supports.

All the mounted skeletons of *Iguanodon* are now complete, and it is anticipated that all the bones exposed in the rock masses will be treated before the end of this year. The skeletons of the associated fossil crocodiles, *Goniopholis* and *Bernissartia*, will then be preserved from decay in the same manner. The Belgian Government and Dr. V. Van Straelen, the director of the Brussels Museum, and his staff, are to be congratulated on their success in an important scientific undertaking. A. S. W.

Obituary Notices

Sir Herbert Jackson, K.B.E., F.R.S.

SIR HERBERT JACKSON, whose death occurred on December 10 after a very brief illness, was born on March 17, 1863. After attending King's College School, he entered King's College, London, in 1879 as a special student of chemistry, and for a number of years he worked both as student and student-demonstrator in Prof. C. L. Bloxam's private laboratory. His association with King's College continued without interruption until 1918. He held successively the positions of lecturer, assistant professor (1902), and professor of organic chemistry (1905); he was elected a fellow of King's College in 1907, and was finally appointed Daniell professor of chemistry on the retirement of Prof. John Millar Thomson in 1914. He was regarded with affection by all the students of the College for the zest with which he participated in their social and athletic activities, which affection was enhanced among those who studied under him by their recognition of his admirable teaching capabilities.

During this period, Sir Herbert Jackson's research activities covered an extraordinarily wide range. He carried out a lengthy investigation into the production of phosphorescent materials, and made an extensive study of the phosphorescent and fluorescent phenomena produced in various materials by ultra-violet light or by electric discharge in low-vacuum and high-vacuum discharge tubes. In the course of his experiments with high-vacuum tubes he observed that in some instances phosphorescent materials in close proximity to the tubes gave a luminous response when the tubes were excited. This observation was not followed up immediately as it did not fall into the general line of investigation which was being pursued at the time, otherwise the discovery of X-rays, which was announced by Röntgen a few months later, might well have been made by Sir Herbert Jackson. Immediately Röntgen's discovery was published, Sir Herbert Jackson constructed an X-ray tube of the type described by Röntgen—the first X-ray tube to be produced in Great Britain—and thereafter he devoted a considerable amount of attention to a study of the effects which could be produced by the 'new' rays and to the development of X-ray tubes of improved forms. The 'Jackson' focus-tube, which he devised—and which he refused to patent—was a development of very great importance, since it provided practically a point source of X-rays and thus ensured sharp definition in X-ray photographs; the curved cathode which was its essential feature was adopted universally.

It is impossible to give any complete account of the many lines of investigation which Sir Herbert Jackson pursued while he was at King's College, but by way of contrast to the foregoing, mention may perhaps be made of two other items. He made a considerable study of the detergent action of alkalis, oils, soaps and chemical solvents, and of their behaviour on fabrics of different types. His work in this direction and the lectures and demonstrations which he gave to special classes for launderers are gratefully remembered by the laundry industry as a whole for their immense practical value. Sir Herbert also brought his scientific knowledge to bear on methods of protecting stonework against weathering action, and for many years devoted a good deal of attention to this important problem.

Sir Herbert Jackson was recognized as a microscopist of the first rank. In the widely varied types of scientific work which he had undertaken he had made very considerable use of his microscope, and he was, in consequence, familiar with the appearances presented under all available types of illumination, by bacilli, crystals, diatoms, fibres, gratings, powders, rulings, metals and all the more usual microscopic objects. He had also made a considerable study of the microstructure of porcelains, glazes, opal and coloured glasses, etc., and his observations, backed by his chemical knowledge, enabled him to draw important and far-reaching conclusions relating to the methods which had been employed in the production of Chinese and other ceramic wares, ancient beads, ancient glasses, etc. He was always ready to place his expert microscope technique at the disposal of others, whether to enable them to acquire some small measure of his skill or to help in the elucidation of problems on which critical microscopic observation might be able to throw some light. In his hands, the microscope was an all-revealing instrument, and it was at once a pleasure and an education to be allowed to join with him when there was microscope work to be done.

Very early during the Great War, Sir Herbert Jackson was asked to advise on a variety of urgent chemical problems, and as the extent of his knowledge and the value of the suggestions which he could invariably put forward became more widely known, his advice was increasingly sought. Chief among his many war-time activities must be counted his experimental work on glasses needed for chemical purposes and for X-ray tubes, and, later, his working out of the formulæ for many types of optical glasses not previously manufactured in Great Britain, but essential for such instruments as gun-sighting telescopes, and other optical munitions. In recognition of his valuable war-work, in particular of his work on glass, he was created Knight Commander of the British Empire in 1917, and was elected to the fellowship of the Royal Society in the same year.

When the British Scientific Instrument Research Association was in process of formation under the research association scheme of the Department of Scientific and Industrial Research, Sir Herbert Jackson was invited to become its first director of research. His versatility and his remarkable experimental ability, combined with his keenly analytical mind and quick grasp of essentials, fitted him admirably for this position. Under his guidance, the Association came to be regarded more and more as a source to which any matter concerning the development or manufacture of scientific instruments could be referred with the certainty that useful suggestions would be forthcoming practically at once, if, indeed, a complete solution of the particular problem submitted could not be immediately put forward. Sir Herbert Jackson filled this position with distinction from 1918 until he rètired in 1933; he afterwards acted as consultant to the Association, and served as a member of the Association's Research Committee up to the time of his death.

Sir Herbert Jackson held office as president of the Röntgen Society (1901–3) and as president of the Institute of Chemistry (1918–21), and was for some years a member of the senate of the University of London. He served as chairman or as a member of many scientific and advisory Committees, including the Adhesives Committee and the Building Research Advisory Committee of the Department of Scientific and Industrial Research, the Interdepartmental Committee on Optical Glass, the Advisory Committee on Research of the L.M.S. Railway, and others of equal importance.

His death removes one who has rendered valuable service in very many fields, and is deplored by all who were privileged to work with him and to be included in his wide circle of friends.

Captain Oscar Wisting

CAPTAIN OSCAR WISTING, the Norwegian arctic explorer, was born in 1871 and at the age of sixteen years went to sea and in 1892 joined the Norwegian navy. His tastes, however, led him to polar seas, and after a few voyages in whalers and sealers he joined the expedition of R. Amundsen in 1909.

This expedition was originally intended to be an arctic venture but on news of Peary's attainment of the Pole reaching Europe, Amundsen decided to change his plans and make for the Antarctic. The *Fram*, Nansen's famous old ship, carried the party to the Ross Sea and their base on the Ice Barrier. Wisting was one of the four men who reached the South Pole on December 14, 1914. Amundsen attributed not a little of their success to Wisting's careful work in making the sledges, clothing and tents for the journey.

Amundsen's next expedition, the exploration of the Arctic Ocean, was delayed by War conditions and the necessity of building a new ship, but when he sailed in 1917 Wisting was his second in command. After three winters in the ice, the *Maud*, making the North-East passage, reached Alaska, only to return for another winter on the Siberian coast, this time in charge of Wisting, who had only three other men with him. After refitting at Seattle, Wisting again took the *Maud* north in 1922 and returned five years later, having failed to penetrate the inner arctic seas.

In 1926 Wisting was one of the men who accompanied Amundsen in the airship *Norge* in its flight of 3,393 miles from Spitsbergen across the Pole to Teller, in Alaska. When Nobile's airship *Italia* came to grief in 1928, Amundsen flew to the rescue from Norway. On the disappearance of his aeroplane Wisting went to Spitsbergen to join the vain search.

In 1926 Wisting retired from the navy with the rank of captain and in recent years had been custodian of the *Fram*, which is now kept on land at Oslo as a polar museum. It was on board the *Fram* that he died on December 4. R. N. R. B.

Señor Don Juan de la Cierva

THE death of Señor Cierva in the accident to a Dutch air liner on December 9 is a grave loss to aeronautical science. Fourteen years ago he invented the main principles of the autogiro, and in the intervening years he was assiduous in working, chiefly in England, on schemes for its improvement. His very latest model, the direct lift type, after being successfully demonstrated, has now reached the point of being built in numbers. Hence its inventor may be said to have lived just long enough to see his invention reach the fullest development attainable by that type of aircraft.

Señor Cierva was born in 1895 at Murcia in Spain. He received his scientific training at the Civil Engineering School in Madrid, and four years later he began his work on rotating wing aircraft, being convinced from his experience of the fixed wing type that the danger of accident by stalling was irremovable by other means. In his new plans he arranged for the peripheral speed of his 'windmill' to be several times as great as the highest horizontal speed of the entire craft, and since this peripheral speed remained nearly constant, the craft could always count on adequate lift, however slowly the machine as a whole might be flying. In fact experiment soon showed that against a modest wind of twenty miles an hour or so, the autogiro could keep station in descent over a definite spot on the ground.

The autogiro could, however, not compete with a helicopter in vertical 'take-off', and it was to this point that Señor Cierva devoted the later years of his life. He devised a mechanism whereby the pitch angle of the rotating blades of the windmill could be changed, and he used this mechanism to change, from a zero pitch angle to a large one, the angle of attack of the rotating blades at the moment of starting flight. This caused the craft literally to jump into the air—as much as 30 feet—and then to climb on a gentle path free from ground obstructions. In this way, the inventor considered that he had added to his autogiro the main advantage claimed for the helicopter of being able to rise from a very small field.

At each stage in the development of his ideas, Señor Cierva gave an account of his work to the Royal Aeronautical Society, of which he was a fellow. From that Society he received its Silver Medal and later the Wakefield and Guggenheim Gold Medals. In his lifetime he always expressed himself warmly on the recognition he received from the Royal Aeronautical Society, as he did on the encouragement given to him by the Air Ministry and the Aeronautical Research Committee, from his earliest flying demonstration to an astonished assemblage at Farnborough until the day of his death.

We regret to announce the following deaths:

Dr. L. Gustave Binger, *correspondant* for the Section of Geography and Navigation of the Paris Academy of Sciences.

Prof. William Campbell, Howe professor of metallurgy in Columbia University, an authority on physical metallurgy, on December 16, aged sixty years.

Prof. Augustus H. Gill, emeritus professor of chemistry in the Massachusetts Institute of Technology, an authority on hydrocarbons, on November 11, aged seventy-two years.

Prof. Edouard J. B. Goursat, formerly professor of mathematics in the Sorbonne, on November 26, aged seventy-eight years.

Dr. Henry B. Hedrick, formerly ballistician in the U.S. Ordnance Department, known for his work on the preparation of mathematical tables, on October 6, aged seventy-one years.

News and Views

Louis-Bernard Guyton de Morveau (1737-1816)

THE bicentenary of the birth of Guyton de Morveau recalls the career of a man of science who was a prominent figure in what is, perhaps, the most interesting epoch in the history of science in France, if not in French history itself. Ingenious, versatile and courageous, he engaged in many enterprises and as a man of science had a wide reputation. Born at Dijon on January 4, 1737, Guyton de Morveau was the son of the professor of civil law in that city. He himself was educated for the law at Dijon and Paris, and after he had practised for a short time, his father procured for him at the price of 40,000 francs the appointment of advocate general to the local parliament at Dijon, which he held for twenty-three years. Always of an inquiring mind, he became attached to the Academy of Sciences in his native city, devoted himself to the study of chemistry—being assisted by Baumé—and in 1776 began to lecture on that subject. He also established on scientific principles a saltpetre factory which was conducted by Courtois, the father of the discoverer of iodine. He became acquainted with the men of science in Paris, and in 1780 he was induced by Panckoucke, the bookseller, to undertake the chemical section of the famous "Encyclopédie Methodique". Seven years later he joined Lavoisier, Berthollet and Fourcroy in the publication of the "Methode de Nomenclature Chimique", which revolutionized chemical nomenclature.

As with so many of his countrymen, at the outbreak of the Revolution, de Morveau's energies were diverted into another channel. He was chosen a deputy to the Legislative Assembly, of which he became secretary in 1791, and president the following year. In the Convention he was one of those who voted for the King's death; and in 1794 he accompanied the army into Belgium and made balloon ascents at the battle of Fleurus. With the return of more settled conditions he was made a professor in the newly founded Ecole Polytechnique, and in 1795 was chosen a member of the Council of Five Hundred, and also one of the forty-eight members of the National Institute which had arisen over the ashes of the old academies. He acted as director of the Ecole Polytechnique during the absence of Monge, who had accompanied Napoleon to Egypt, and he continued to lecture there until he was seventy-six years of age. He was made a baron in 1811, and died in Paris on January 2, 1816. The range of his writings can be seen from the list of more than 190 papers appended to the biographical sketch of him by Thomas Young in the earlier editions of the

"Encyclopædia Britannica". He was one of the first to be converted to Lavoisier's views on combustion, and did much to make known the advances made by French chemists. No great discovery is associated with his name, but his influence on the progress of chemistry was far reaching.

Mr. G. C. Robson

ZOOLOGISTS, especially those interested in the study of Mollusca, will learn with regret that Mr. G. C. Robson has been compelled by ill-health to resign from the scientific staff of the British Museum (Natural History). Mr. Robson went to the Museum from Oxford in 1911 as an assistant in the Department of Zoology, and devoted his attention to the Mollusca, studying more especially their anatomy and ecology. Among his more important works were his account of parthenogenesis in the gasteropod *Paludestrina* and his contributions to the systematics of the Cephalopoda, especially the Octopoda, on which he wrote a monograph published in two volumes by the Museum in 1929 and 1931. His interest in the more general aspects of biology is shown in his book "The Species Problem" (1928) and in the recent volume "The Variation of Animals in Nature" (1936), in which he collaborated with Dr. O. W. Richards. In 1931 he was appointed one of the two deputy keepers in the Department of Zoology. Mr. Robson's work at the Museum has brought him into contact with malacologists all over the world, and his many friends will hope that freedom from official responsibility will bring about his restoration to health and to scientific activity.

Messel Research Fellowship

DR. J. E. HARRIS, of Christ's College, Cambridge, has been awarded a Messel research fellowship in biology by the Royal Society as from January 1. Dr. Harris held a Commonwealth Fund fellowship at Columbia University and the Guggenheim School of Aeronautics in 1933–35, and has since been University demonstrator in zoology at Cambridge. He proposes to investigate how far current morphological views on the evolution of the fins of fish are substantiated by a study of the functions of these organs. From an analysis of the effect of the fins on an accurate model of the dogfish suspended in a wind tunnel, it has been found possible to draw fairly definite conclusions concerning the action of these fins on the static stability of the living fish. It seems likely that an extension of these methods to other types will throw light on the relationship between the form of the fins and the habits and possible course of evolution of the different groups. The work will be combined with a study of the neuromuscular mechanism and of the forces produced by actively moving fins, the methods available for such study having already proved adequate. It is hoped that time will also permit of the confirmation and interpretation of Dr. Harris's somewhat striking observation, that there exists in the nucleus of the unfertilized egg of echinoderms a physical polarity which can be demonstrated by observations on the rate of free fall of the nucleolus in the germinal vesicle. Dr. Harris will work at Cambridge and possibly also at the Tortugas Laboratory of the Carnegie Institution of Washington, and the Guggenheim School of Aeronautics, New York.

The British Broadcasting Corporation

THE present British Broadcasting Corporation was granted its first charter of incorporation on December 20, 1926, and a supplemental charter on August 14, 1931. The special Committee, which was set up by the Postmaster-General, has recently conducted an inquiry into the broadcasting service and has recommended that the service should continue to be developed and exploited to the best advantage and in the national interest. This action is very desirable on account of the widespread interest in broadcasting, as illustrated by the fact that more than seven and a half million persons in Great Britain and Northern Ireland now have licences to instal apparatus for the reception of broadcast programmes. Accordingly, the British Broadcasting Corporation will continue in being under a new charter which came into operation on January 1, 1937, the draft of which has recently been published by H.M. Stationery Office as Cmd. 5329 (4*d.* net). In this paper, the objects of the Corporation are described in some detail; briefly, they may be summarized as the development, exploitation and maintenance of a public utility service for broadcasting to the public by means of wireless telephony and television any matter of interest, which may be permitted within the terms of the licence and agreement between H.M. Postmaster-General and the B.B.C. The draft of this licence is also included in the White Paper referred to above. The charter outlines the organization of the Corporation by means of a chairman, vice-chairman and body of governors, and the chief executive officer of the Corporation is the director-general. The Corporation is authorized and empowered to receive and administer the funds granted annually by the legislative for the objects in view, and provision is made for the submission of an annual report and statement of accounts. To the lay mind, it is satisfactory to note from this paper that the broadcasting service in Great Britain will continue to maintain its unrivalled reputation, controlled and yet not hampered by Government administration, free to develop and exploit to the full the technique of broadcasting by both sound and vision.

Salvador Earthquake of December 20

FOR its size, the small republic of Salvador, containing only 7,225 square miles, has been visited by great destructive earthquakes more frequently than any other country. During the nineteenth century, there were at least fifteen such earthquakes, and Montessus records the ruin of San Salvador eleven times between 1538 and 1854. San Vicente, a town of 26,000 inhabitants and lying about 35 miles to the east of San Salvador, has suffered from earthquakes several times during the last century, and was almost ruined by a violent shock on the morning of December 20. With one exception, all the important buildings in the town have been thrown down, but, fortunately, without any outbreak of fire. The loss of life and property is not yet definitely known, as communications with the capital are almost destroyed, but, according to official estimates, 220 persons have been killed. It is feared that, as in 1835, there may also be an eruption of the neighbouring volcano.

Bushman Hybrids

IN another column of this issue of NATURE (see p. 37) a summary is given of a short paper by Dr. T. F. Dreyer of Bloemfontein on "The Significance of the Bushman Skull", of which the importance for the anthropologist, the sociologist and in the long run possibly also for the statesman, is by no means to be gauged by its brevity. It opens up a wide vista of further research and inference on the all-important question of miscegenation. Students of the effects of racial contact and admixture, from lack of positive and unequivocal evidence, have long hesitated to endorse the popular verdict that cross-breeds in man have the vices of both parent races and the virtues of neither. They prefer, or rather are forced, to attribute the observed defects in character of such hybrids, and especially of hybrids between white and coloured, to the environmental influence of the social conditions to which as a rule they are confined, rather than to any inherent hereditary weakness. Some, perhaps, would go so far as to concede the possibility that extreme diversity in physical make-up of two widely separated races in the parents may react unfavourably in the offspring; but on the whole, notwithstanding the results of a number of investigations, judgment has more or less remained in suspense.

DR. DREYER's study of the processes of growth which have produced the characteristic Bushman skull suggests a line of research, which, if it should yield results analogous to those observed in Bushman hybrids, will afford grounds for the conclusion that hybridization of certain types may produce specific modification of structure and function, which being abnormal, may be presumed to be unfavourable to the organism as a whole. The Bushman hybrids observed by Dr. Dreyer showed in their abnormal development in the direction of acromegaly or the reverse condition the result of a disturbance of the function of the pituitary—an inference supported by evidence that that body was either over- or under-developed. Should further research show this conclusion to be of general application, it will do much to remove at least one line of argument in the discussion of racial contact from the influence of racial prejudice.

Bronze Age Cemetery near Glasgow

AN important addition to the record of recent finds of prehistoric age in the neighbourhood of Glasgow is a bronze age cemetery site at Springhill Farm, Baillieston, identified and examined by Mr. J. Harrison Maxwell and other members of the Glasgow Archæological Society. The first indication of the site was the unearthing of two food vessels in May last by workmen, when excavating a hillock for sand and gravel. Of these two vessels, one, according to a description in *The Times* of December 21, was in perfect condition. It was hand-made and of reddish brown clay, with two zones of decoration made by string impression, the upper zone in horizontal, the lower in vertical or slightly oblique lines. The second vessel, unfortunately broken by the workman in digging, but now skilfully restored, is of a more elaborate and beautiful character. Its rim is bevelled inward, and for ornament it has an upper zone of decoration formed by horizontal rows of impressions of barley ears, while elsewhere are impressions or punch marks made by the end of a hollow bone, stick or reed. This discovery led to a careful watch on the progress of excavation, and a number of burials, seven cremated and two inhumed, were recorded. The most important discovery, however, was that of a bronze age cist of unusual type in that instead of two long and two short stones, it is built of a large number of small stones and is tongue-shaped, about four feet long and two feet broad at its greatest breadth. The cover consisted of two large stones, that to the south being very thick, while that to the north had an oblong cut-out on the east side. The floor was a pavement of water-rolled pebbles. There were two cremation burials on top of, and two inside the cist. Discoveries of bones and a burial were made in November and December, of which the latest has not yet been excavated. The bones are under examination. Two square-shaped pits containing iron slag point to the existence of a later 'bloomery' or forge.

Roman Sussex

A DISCOVERY of Roman remains, of interest for its topographical bearing, is reported from West Sussex. Workmen, while laying a water-main from Wickford Bridge, east of Pulborough, to Hurston Farm, discovered Roman walls of rough sandstone, and bonding courses of Roman tiles at a depth of 1–7 feet. They lay just north of Lickfold along the west side of the Wiggonholt Road. According to the account given by the workmen, as reported in *The Times* of December 24, two walls running parallel to the road and about fifteen feet in, formed a passage, at the end of which was a small square apartment. From the character of the red burnt sandstone and flue tiles thrown out, it is considered reasonable to infer that this had been a stoking chamber and hypocaust belonging to a house site, similar to one of which there are indications one hundred yards away. Surface finds of pottery belong to the turn of the first and second century. The importance of the find lies in the fact that it corroborates the identification of the modern road as being on the line of the Roman road from Stane Street at North Heath, Pulborough, by Wiggonholt to the South Downs north of Storrington. The great depth at which the remains were found is due, it is suggested, to the drift of light sandy soil on a down slope.

The Ministry of Health

THE seventeenth annual report of the Ministry of Health, recently issued, summarizes the work of the Ministry during 1935–36 (London : H.M. Stationery Office, 1936. 5*s.* net). The services administered by the Department involved expenditure amounting to £159,500,000. About one expectant mother in every two now makes use of local authorities' facilities for ante-natal examination, a steady increase on previous years. Maternal mortality was 3·93 per 1,000 births, the lowest figure since 1924. Infantile mortality, that is, deaths of infants less than one year of age, was 57 per 1,000 births, the lowest figure on record. The total deaths from all forms of tuberculosis fell below 30,000 for the first time on record. Of other infectious diseases, diphtheria showed some decline in 1935, only one case of smallpox was notified in that year, the deaths from pneumonia were nearly 1,000 fewer, and scarlet fever and measles were less prevalent. Much progress is reported in slum clearance, abatement of overcrowding, and in town and country planning. As regards public assistance, progress continues to be made in eliminating small and old-fashioned country institutions, and vagrancy appears to be steadily declining. Some 11 million men and 5¼ million women in England and Wales are now entitled to health insurance benefits, upon which £27,780,000 was spent in 1935. The annual State contribution for widows, orphans, and old age pensions grows automatically by one million a year until 1943, and is now (1936–37) £15,000,000. The section upon food gives information on new administrative measures, and details of the examination of 143,831 samples of food and drugs, of which 7,972 were given adverse reports.

The Nation's Health in 1935

THE seventeenth annual report of the Chief Medical Officer of the Ministry of Health, which was published on December 4, covers the year 1935. The deaths numbered 477,401, an increase of 591 over 1934, the principal certified causes of death at all ages being, in order, (1) diseases of the heart and circulatory system, (2) cancer, (3) bronchitis, pneumonia and other respiratory diseases. Attention is directed to the changing age-distribution of the population. Since the beginning of the century, the proportion of persons under twenty-five years has fallen by nearly twenty-five per cent, due to the fall in the birth-rate, and the fall in the general death-rate, which increases the proportion in the older groups. This increasing longevity of the population, together with more accurate diagnosis, probably accounts for the increase of the number of deaths from cancer, which is a disease of the later ages, from 63,263 in 1934 to 64,507 in 1935, and it is probably fallacious to assume that there is a real increase of cancer. For 1935, the incidence of scarlet fever, diphtheria, tuberculosis, venereal and rheumatic diseases has declined, and only one case of smallpox was notified. Attention is directed to the relation of food to health and disease, and to the extension of the maternity and child welfare services.

Was Sherlock Holmes a Drug Addict?

AN occasional correspondent contributes an amusing article to *The Lancet* of December 26 entitled "Was Sherlock Holmes a Drug Addict?", as his friend Dr. Watson represented him as being. The correspondent's reply is in the negative on the following grounds. In the first place, Holmes was a man of immense mental resource and initiative, being an expert chemist, an accomplished linguist, an assiduous student of Black Letter texts, a capable performer on the violin, a composer and an authority on medieval music. Nor was he of the stuff of which cocaine addicts are made, who are sociable, lacking in mental capacity and need the stimulus of a drug to rouse their interest in life. The continued use of cocaine leads to physical, mental and moral degeneration. Holmes, on the other hand, was the most unsociable of men and showed no deterioration in his mental powers, physical activity or character. The correspondent suggests that Holmes was playing a trick on Watson when he pretended to give himself an injection of cocaine and showed an arm dotted and scarred with numerous puncture marks.

Institute for the Study of Animal Behaviour

AN Institute for the Study of Animal Behaviour has been formed by a number of zoologists, naturalists, physiologists and psychologists with the object of promoting and encouraging research into animal behaviour. The Institute intends to act as a clearing-house for information regarding work that is being done upon animal behaviour in all its aspects, and to bring together field and laboratory workers for the discussion of their problems. A quarterly bulletin is being issued, and meetings for the transaction of scientific business are held. Those whose work is concerned with animal behaviour in any of its aspects will materially assist the work of the Institute if they will send offprints of their papers to the honorary secretary. Dr. J. S. Huxley is president of the Institute, and Mr. F. B. Kirkman is honorary treasurer. All information regarding membership and activities may be obtained on application to the honorary secretary, R. C. Oldfield, Psychological Laboratory, Downing Place, Cambridge.

The Making of Chemical Plant

THERE is a school of economics which lays stress on the importance of exports in order that Great Britain may pay for its imports. At the same time, the home manufacturers ask for some measure of protection so that they can supply the home markets and maintain a manufacturing plant of sufficient size to ensure reasonable costs. An industry which has progressed quite rapidly in Great Britain since the Great War is that of making chemical plant, about which the *Industrial Chemist* of November has published some interesting statistics. The export trade has gone up from a figure of 100 in 1933 to 131 in the first nine months of 1936. The plant exported goes to less highly industrialized countries and, therefore, is not of the same complexity and costliness of design which the home market demands :

R 269

thus the average value this year is £67 per ton. Australia and South Africa are now the chief customers for British chemical plant. Great Britain also imports chemical plant, and since there is increasing activity in the chemical industry, the amount of this has increased more than three-fold since 1935, though there are now signs of abatement. The average value per ton this year is £143. Most of the plant, which is generally of a highly specialized nature, has come from Germany. These figures give no indication of the activities of the British plant manufacturers in the home trade, but the same number of the *Industrial Chemist* seeks to remedy this by several pages of pictures of actual plant and new equipment which has been delivered this year, featured under the heading of "Progress".

Forest Products Research

THE report of the Forest Products Research Board for the year 1935 has been issued by the Department of Scientific and Industrial Research (London : H.M. Stationery Office, 1936). The report includes the report of the director of the Research Laboratory at Princes Risborough for the same year. The Board itself met only once during the year, when various pieces of research work under investigation were considered, as also the possibility of establishing a sub-station of the Laboratory in Scotland. The Board noted with appreciation that there was direct evidence of interest by industries concerned in the manufacture of both wooden and fibre-board boxes, as well as by users of such boxes, of the facilities now available in the new box-testing laboratory. The investigations into the physical properties of timber which have a direct influence on its behaviour during seasoning and when in use have been advanced ; and the results, it is considered, promise ultimately to be of material importance to architects and others engaged in industries dependent upon timber. As a result of visits to the Laboratory by many representatives of firms engaged in the manufacture of timber and timber goods, and instructors in building science or woodworking at various technical schools, some of whom have spent periods of varying lengths at the Laboratory, a new departure has been instituted. To minimize the interference with the routine work which such visits involved, a short educational course of one week's duration was given in September of which full advantage was taken.

An Alchemical Manuscript

IN a reprint from *Osiris* (2, 220; 1936), W. J. Wilson, of the Library of Congress, Washington, deals with a treatise copied by Arnaldus de Bruxella at Naples between 1473 and 1490, and purchased by Lehigh University, Pennsylvania, in 1881 for the price of ten dollars. It is a compendium of chemical and alchemical recipes of a type fairly well known through other manuscripts of similar date in Paris and elsewhere. Mr. Wilson gives an account of the contents of the manuscript with extracts, which are translated, and an index of names and technical terms. He shows how its contents are related to other treatises, and deals in separate sections with the origin and development of alchemical tradition, the operations of alchemy, allegorical and mystical aspects of alchemy and its relations to magic and medicine. This commentary, which is the fruit of a careful study of texts and literature on the history of alchemy, is provided with an excellent bibliography and is of very considerable value in presenting an accurate and concise statement of the position of modern research into the origins of alchemy and early chemistry. The scholarly treatment is on a much higher level than many accounts in that it takes into consideration the Chinese and Indian sources, without which no modern study can be said to have any particular significance.

Decline in Malaria in Soviet Russia

As the result of the energetic measures adopted by the Soviet authorities, the incidence of malaria in the U.S.S.R. has greatly declined. According to Prof. Sergiyev, head of the Malaria Department of the Commissariat of Health and director of the Central Tropical Institute, during the first six months of 1936 there was a drop of about 35 per cent in the number of malaria cases and of 40 per cent in the number of deaths from malaria as compared with the corresponding period of 1935. With the object of destroying the malaria-carrying mosquitoes, two and a half million infested areas were sprayed with oil, partly by aeroplanes. Mosquito netting was introduced into the badly infested areas. 100 motor-cars and 260 microscopes were supplied to the malaria stations. During the summer, 500 doctors and senior students took part in the anti-malarial campaign, which was carried on by 1,800 permanent malaria organizations.

Tropical Pathology and Microbiology

OWING to the increasing number of papers in the field of special pathology and microbiology hitherto published in the *Chinese Medical Journal*, which is primarily intended for clinical contributions, this material will now be published in a Supplement to the *Chinese Medical Journal*, of which the first number was issued last February. It forms a volume of the same size and format as the *Journal*, and contains 500 pages of text with 70 plates, and is published by the *Chinese Medical Journal*, Peiping, China, price 10*s*. The contents are divided into the three subjects : (1) pathology, (2) bacteriology and (3) parasitology. In addition, there is a valuable paper by R. J. C. Hoeppi on "Methods of Illustrating Scientific Papers", in which the apparatus for, and technique of, drawing, and the main processes now used for reproduction of illustrations, are described.

Museum Exhibits *de luxe*

AT last the limit of the nature-group method of exhibiting museum specimens seems to have been reached, for Science Service announces that Prof.

A. A. Allen, of Cornell University, has constructed two life-groups of birds, in which by a combination of sound films and ingeniously contrived electrically driven mechanisms, the birds sing and go through natural, life-like movements. For example, in the group showing a nesting site of ruffed grouse, the turning of a switch causes the male to move his head and utter his characteristic hissing note, while the female moves to her nest and covers her eggs, and at the same time thrushes and song-sparrows in the trees and bushes sing, an owl hoots, a woodpecker calls and dives into its nesting hole, and a wedge of wild-geese honks as it flies away. These exhibits must be a revelation to the person who has not the opportunity or the flair for field observation, and, with Prof. Allen's assistance, the arm-chair naturalist will soon be able to record his impressions of life in the wilds from a museum exhibit.

Honey Research at Rothamsted

THE Agricultural Research Council has recently made a substantial grant to Rothamsted to permit beekeeping researches there to be broadened to include the investigation of various problems connected with honey. The appointment of Dr. C. R. Marshall to undertake this work has been approved, and Dr. Marshall has now taken up his duties. In view of the fact that beekeepers during the past three years have contributed towards the cost of the brood disease investigations, the Government is bearing the whole cost of this new work. The researches on honey will be physico-chemical in nature, and directed towards certain practical problems of quality and processing that affect the honey producer. Such problems are the granulation of honey, rapidity of granulation, texture of grain, 'frosting', etc., and fermentation. Dr. Marshall recently obtained the degree of Ph.D. at the University of Birmingham, where he has been working on chemical problems connected with the structure of mucilages.

International Congress on Testing Materials

THE next International Congress of the International Association for Testing Materials will be held in London on April 19–24, under the presidency of Sir William Bragg (see NATURE of October 24, p. 717). More than two hundred papers are promised from authorities in twenty different countries. The Congress will be divided into the following groups: metals (behaviour of metals as dependent upon temperature, particularly in regard to high temperatures; progress of metallography; light metals and their alloys; wear and machinability); inorganic materials (concrete and reinforced concrete; erosion and corrosion of natural and artificial stone; ceramic materials); organic materials (textiles; wood cellulose; timber preservation; ageing of organic materials; colours and varnishes); subjects of general importance (relation between results of laboratory tests and behaviour in use and service; bearing of recent advances in physics and chemistry on the knowledge of materials; properties of materials for the thermal and acoustic insulation of buildings). Further information can be obtained from the Honorary Secretary of the Congress, K. Headlam-Morley, 28 Victoria Street, London, S.W.1.

Exhibition of Scientific Instruments

IN connexion with the twenty-seventh annual Exhibition of Scientific Instruments and Apparatus to be held at the Imperial College of Science on January 5–7, the usual well-produced and substantial descriptive catalogue of exhibits has been prepared (Physical Society, 1 Lowther Gardens, Exhibition Road, S.W.7). Trade exhibits are separated from the Research and Educational Section: apparatus and instruments being exhibited for the first time are indicated by an asterisk. Reference is facilitated by the full list of contents and an index to the Trade Section. The Exhibition is open on January 5 (2.30–9), January 6 (2–4 for members only; 4–9) and January 7 (2.30–9); admission is by ticket obtainable from the secretary of the Physical Society. Evening discourses are being given at 7.45 on January 5 by Sir James Swinburne on electrical measurements in the 'eighties, and on January 6 by Dr. Harry Moore on the influence of industrial research on the development of scientific instruments.

Announcements

THE Electrodepositors' Technical Society has decided to sponsor an International Conference on Electrodeposition to be held in London on March 3–4. The provisional programme includes discussions on electrodeposition practice abroad, electrodeposition of base metals, properties of electrodeposits and electrodeposition of precious metals. Further information can be obtained from the Hon. Conference Secretary, Mr. H. Wynne-Williams, 12A Raleigh House, Larkhall Estate, London, S.W.8.

IN connexion with the Electric Illumination Exhibition now being held at the Science Museum (see NATURE of December 19, p. 1046, and December 26, p. 1107), a series of six lectures has been arranged to be given in the lecture theatre of the Museum at 5.30 p.m. on Tuesday, January 12, and thence on Mondays commencing January 18. Admission will be by ticket obtainable from the Secretary, Science Museum, London, S.W.7.

OWING to the conditions in Spain, the eleventh International Congress of Psychology which was to have been held in Madrid (see NATURE of July 4, p. 24) will be held in Paris. So far as possible, the programme will be the same as that previously arranged for the proposed meeting in Madrid. The Paris Congress will be held on July 25–31, under the presidency of Prof. Pierre Janet, formerly professor of psychology in the Collège de France. Further information can be obtained from M. Henri Pieron, Laboratoire de Psychologie de la Sorbonne, Paris 5.

THE announcements of forthcoming appointments will appear in future at the end of each issue (see p. 42).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 32.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

α-Particles from the Radioactive Disintegration of a Light Element

WHEN lithium is bombarded with deuterons, a radioactive substance is formed which has been found to emit β-rays with energies up to 10·5 Mev.[1]. We have recently found that this radioactivity is accompanied by the emission of α-particles.

The reactions proposed to account for the β-ray activity were:

$$^{7}\mathrm{Li} + {}^{2}\mathrm{D} \rightarrow {}^{8}\mathrm{Li} + {}^{1}\mathrm{H}\ ;\ {}^{8}\mathrm{Li}\ (\text{radioactive}) \rightarrow {}^{8}\mathrm{Be} + e^{-}.$$

From our knowledge of nuclear masses, the expected total energy release in these two reactions should be 14 Mev., but this has not all been accounted for hitherto.

The protons liberated in the first reaction were formerly supposed to have a range of 26 cm., but the group of this range has been shown by Rumbaugh and Hafstad[2] to be a product of the bombardment of the separated isotope ^{6}Li with deuterons. We had also independently obtained the same result. We have also found, in agreement with Rumbaugh and Hafstad, that the bombardment of ^{7}Li with deuterons gives rise to no group of protons of range greater than 8 cm. (2 Mev.). This means that the energy release in the first reaction must be less than 2 Mev., and taking this with the β-ray energy of 10·5 Mev., we have a maximum total energy of only 12·5 Mev., which is considerably less than the expected 14 Mev.

A possible explanation of this is that the ^{8}Be is formed in an excited state. Dee and Gilbert[3] have obtained evidence for such a process in the reaction

$$^{11}\mathrm{B} + {}^{1}\mathrm{H} \rightarrow {}^{8}\mathrm{Be} + {}^{4}\mathrm{He}.$$

They concluded that the ^{8}Be nucleus was often formed in an excited state having 3 Mev. excess energy, and Mr. Dee suggested that we should see whether we could obtain evidence of this excited ^{8}Be also being formed in the radioactive disintegration of ^{8}Li. The life-time of the excited ^{8}Be nucleus being negligible (10^{-21} sec.)[1], we should expect to observe α-particles resulting from its disintegration accompanying the emission of electrons from ^{8}Li and decaying with the same period.

This may account for the α-particles which we have observed, for we find that the period of the α-particle activity is identical with that of the β-ray activity and is 0·88 sec. ± 0·1 sec. There is a discrepancy between this figure and that (namely, 0·5 ± 0·1 sec.) given by Crane, Delsasso, Fowler and Lauritsen, who discovered the β-ray activity. Absorption measurements confirm, however, that we have observed the same β-ray activity.

We have observed both the α- and β-ray activity from a target of the separated isotope ^{7}Li kindly prepared for us by E. L. Yates.

Most of the observed α-particles have a range less than 1·5 cm. of air from the target, but a few (less than 0·3 per cent of the total number) extend to a range of 5 cm. The numbers, however, are small at the higher ranges, so that the limit of range has not been determined exactly. As an illustration of the order of magnitude of the effect, it may be noted that after bombarding a thick lithium target with a magnetically resolved beam of 20μa. of deuterons at 500 kv. we observe 50 α-particles of range greater than 1 cm. after switching off the beam.

From the range distribution of α-particles it appears that ^{8}Be is not always formed in the same excited state, but either in a number of discrete energy states or in a continuous distribution. Owing to the small number of particles it has not yet been possible to decide between these hypotheses.

The relative number of α-particles and β-rays suggests that if the interpretation be correct, the ^{8}Be is formed in an excited state in a large proportion of the disintegrations of ^{8}Li. Further, it may be noted that the energy of two α-particles of 5 cm. range amounts to 12·6 Mev. On the view put forward, the spread of α-particle energies cannot exceed the spread of β-ray energies, namely, 10·5 Mev., and it therefore follows that the minimum energy of the two α-particles is not less than 2·1 Mev. In other words, the minimum energy with which the ^{8}Be nucleus is left excited is not less than 2·1 Mev.

While this interpretation appears consistent, it is not the only possible explanation. In any event, it is clear that the distribution of β-ray energies must be interpreted with caution, as the radioactive disintegration is certainly not simple.

Longitude Effect of Cosmic Radiation and the Position of the Earth's Magnetic Centre

THE theory of the allowed cone of electrically charged primary cosmic rays, developed in a number of recent papers by Lemaître and Vallarta[1], is competent to account for the longitude effect if due regard is paid to the fact that the earth's centre does not coincide with its magnetic centre[2]. Assuming Schmidt's determination[3] of the latter and, with Clay, an exponentially decreasing energy distribution of primary charged particles, it has been shown that the longitude effect along the geomagnetic equator should be roughly sinusoidal with maximum at geographic longitude 12° W. and minimum at 168° E.;

the intensity difference between maximum and minimum is calculated to be about 8 per cent. More recent calculations of the position of the earth's magnetic centre (Bruins[4], Bartels[5]) have somewhat revised Schmidt's earlier result, but the theoretical longitude effect is not much affected thereby. The longitude of the maximum and minimum depends *only* on the co-ordinates of the earth's magnetic centre, particularly on its longitude; the intensity difference between the maximum and minimum is closely connected with the distance between the earth's centre and its magnetic centre, to a lesser extent with the energy distribution of primary particles.

In a recent important contribution, Hoerlin[6] concludes that the calculated intensity difference between the maximum and minimum equatorial longitude effect is in good agreement with experiment, but the calculated longitudes of the maximum and minimum are not. Instead of a maximum off the west African coast at 12° W., he suggests that it probably is off the South American coast in the Pacific Ocean at about 80° W., with a corresponding minimum near the Malay Peninsula at 100° E. He concludes in this sense not only from his own measurements, but also from an examination of Compton's chart of lines of constant total intensity[7] which, however, would locate the maximum still farther west.

That there are yet serious discrepancies between sea-level intensities measured by different observers becomes obvious if one compares Millikan and Neher's chart[8] with Compton's, and this disagreement persists if one compares the Pasadena results with either Hoerlin's or Clay's (and his collaborators)[9,11], although there seems to be fairly good accord between the last two. This state of affairs is forcibly brought to the fore if one attempts to fit a continuous curve to represent the experimental data along the geomagnetic equator and then proceeds to its harmonic analysis. In particular, the half-period harmonic, which one would expect if the quadripole component of the earth's magnetic field were important, comes out just about of the same amplitude as the higher harmonics which must be attributed to experimental errors.

There are two relevant experimental results which seem to militate against Hoerlin's conclusion. The first is derived from Bowen, Millikan, Korff and Neher's measurements[10] at altitudes up to 26,000 ft. in the Philippines and in Peru (essentially along the geomagnetic equator), which clearly indicate that the intensity difference between these two points is about 4 per cent and persists up to the highest altitude. The second is the existence of a minimum of intensity off the western coast of South America and somewhat to the north of the geomagnetic equator, shown by Clay, Bruins and Wiersma's measurements of the latitude effect[11] and by Johnson's counter measurements of vertical intensity[12]. These results agree with the theory of the longitude effect referred to above and therefore also with Schmidt's calculation of the earth's magnetic centre. Further, the former result, if confirmed, would establish the absence of photons in the primary radiation.

If, however, one accepts Hoerlin's suggestion, the conclusion seems inescapable that there is a serious discrepancy between the position of the earth's magnetic centre as determined from magnetic and from cosmic radiation measurements, particularly as regards its longitude. The former locate it at about 160° E., whereas the latter would tend to place it at not more than 100° E. Whether this discrepancy is real is a thorny question which we cannot risk to answer. The main purpose of this letter is to direct attention to the present evidence in the hope that further intensity measurements of cosmic radiation, particularly along the geomagnetic equator, and also perhaps a careful analysis of available experimental results, may help to solve the difficulty.

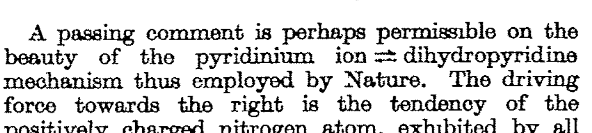
Correlation of the Yellow Oxidation Ferment with Warburg's Co-ferment

THE nature of the yellow oxidation ferment, and of Warburg's co-ferment, having been largely elucidated by the work of Warburg, Kuhn, Karrer, and others, it may be of assistance in completing their correlation if attention is directed to the precise nature of the changes in which they participate.

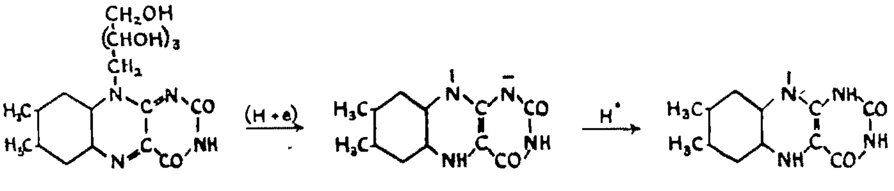
Some time ago[1], in a criticism of suggestions made by Haber and Willstatter, I emphasized that Wieland's dehydrogenation of alcohols and aldehyde hydrates frequently, if not always, consists in the removal, not of two hydrogen atoms, but of a proton and of a hydrogen atom associated with an electron. In illustration, the oxidation of the methoxide anion by nitrobenzene was cited:

$$C_6H_5N(O)O + HCH_2O' \longrightarrow C_6H_5N{=}O + OH' + CH_2O$$

The ferment changes must evidently belong to this class since, in spite of references[2] to the absorption of two hydrogen atoms, the reduction of quaternary pyridinium cations to the neutral dihydropyridine derivative clearly requires addition of a hydrogen atom and an electron. The reaction between a hexose derivative and the quaternary nicotinium amide is to be formulated as follows:



A passing comment is perhaps permissible on the beauty of the pyridinium ion ⇌ dihydropyridine mechanism thus employed by Nature. The driving force towards the right is the tendency of the positively charged nitrogen atom, exhibited by all ammonium compounds, to revert to the neutral tervalent condition, whilst the resulting dihydropyridine tends to recover the aromatic condition by a return to the pyridinium state. This latter is achieved by transference of a hydrogen atom and an electron to the lactoflavin derivative, and there is a recognition of this by Karrer and his collaborators[3] in their formulation of the oxidation of the dihydro-derivative by potassium ferricyanide. But whereas the change studied by them appears to take place in two stages, the formula of the lactoflavin derivative readily accommodates a single-stage process, for it is well known that αβ-unsaturated ketones, $R_2C = \overset{|}{C} - \overset{|}{C} = O$, exhibit kationoid reactivity, for example, towards cyanide ions, at the β-carbon atom. Applying this to the $- N = \overset{|}{C} - \overset{|}{C} = O$, or, perhaps better, to the $- N = \overset{|}{C} - \overset{|}{C} = N - \overset{|}{C} = O$, grouping in lactoflavin, we have



The change is completed by addition to the 1-nitrogen atom of the proton from the original hexose hydrate.

These considerations also point to a possible interpretation of the function of the methyl groups in the lactoflavin molecule, which is so far not understood. For the grouping in question might also be expected to exhibit the familiar property of nitro-groups in promoting anionoid attack in the ortho- and para-positions of the benzene nucleus. On the other hand, methyl groups in the nucleus, and obviously especially so in the para-position, militate against such an attack, and thus tend to localize it on the nitrogen atom. Accordingly, whereas 9-*d*-1′-ribityl*iso*alloxazine itself exhibits no vitamin B_2 effect[4], its 7-methyl derivative does[5]. The influence of other alkyl groups or of methyl groups in other positions has not yet been recorded.

Corticosteron, a Crystallized Compound with the Biological Activity of the Adrenal-cortical Hormone

IN 1929–30 it was found that the cortex of the adrenal gland produces a hormone essential for life[1]. Several attempts have since been made to isolate it in pure form.

Kendall *et al.*[2] announced (1934) the isolation of crystals (m.p. 210°) which were claimed to have the activity of the hormone. They later wrote[3] that the problem was more complex, that their earlier described crystals were a mixture, and that for complete hormonal activity at least two components were essential. In their latest communications[4] they report the isolation of several compounds (*A–E*) one of which (compound *E*, m.p. 201°–208°) "showed definite cortical hormone activity when tested on the rat (Ingle's method)" but that "the quantitative activity of compound *E* is much less than of cortin itself".

Wintersteiner and Pfiffner[5] described six different crystallized compounds (*A–F*), all of which were inactive when tested on adrenalectomized dogs by the method of Swingle and Pfiffner[6].

Reichstein[7] reported the isolation of nine substances (*A–I*), eight of which were found inactive in doses of 0·5–2 mgm. in rats (method of Everse–de Fremery[8]). Only the ninth, substance *H*, has in the meantime been found to be active. This substance, however, was not quite pure. After the elimination of a small amount of a new, high melting substance (substance *M*, m.p. 205°–208°), a pure compound in beautiful crystals was obtained from the remainder. It shows to a large extent the biological activity of the raw material and is called corticosteron (m.p. 180°–182° (corr.), $[\alpha]_D^{18} = +223°$, $c = 1·12$ in abs. alcohol). With the exception of a few details the chemical constitution has been elucidated; the formula will be reported in the near future.

Adrenalectomized rats require a daily dose of 0·5–1 mgm. corticosteron per rat (method of Everse–de Fremery). This amount represents the approximate rat unit and is the biological equivalent of 1 c.c. of commercial 'cortin' (corresponding to 50 gm. of fresh gland) for rats. The experiments on bilaterally adrenalectomized dogs gave similar equivalent values, but since the method of testing used was somewhat different than that of Swingle and Pfiffner, the activity cannot be expressed in terms of dog units.

The curative and preventive properties were tested on four dogs (body weight ranging from 11 kgm. to 18 kgm.) which had been adrenalectomized ¾–1½ years previously. During this period, they received a daily oral dose of 0·3–0·4 gm. sodium chloride per kgm. body weight and the necessary amount of commercial 'cortin' (2·5–5 c.c. per dog per day). Without the salt, about ten times as much 'cortin' was necessary. The complete withdrawal of 'cortin' caused the animals to fall into insufficiency, even if the salt dose were considerably increased. In the curative tests, three to six times the preventive doses of 'cortin' were necessary to bring the animals back to normality from their state of insufficiency. In the various experiments on dogs, an average range of 0·25–0·5 mgm. corticosteron was found to be equivalent to 1 c.c. of the standard 'cortin' solution.

These experiments show that corticosteron is a highly active cortical hormone, but the existence of other active or at least activating components is still possible.

Two New Chemical Plant Growth Substances

BENZOYL oxide and benzoyl peroxide, as I have found, can now be added to the list of chemicals which act on plant growth like the natural hormone, auxin. Benzoyl oxide, when applied in lanoline at concentration 1 in 200 to ten dark-grown decapitated oat coleoptiles along one side, caused negative curves the mean of which was 50° after 4½ hours at 19° C. The peroxide applied similarly caused negative curves the mean of which was 31°. Thus both substances accelerated growth strongly. At 1 in 2,000 in lanoline, the benzoyl oxide caused slight negative curves of about 5°, and comparison with the curves caused by very dilute hetero-auxin in lanoline showed that the activity of benzoyl oxide is very roughly equal to 1/400 of that of hetero-auxin. The oxide keeps well in lanoline, but the peroxide loses its activity in a few hours.

The results seem of interest since first, benzoic acid is quite inactive, and secondly, the benzoyl oxide and peroxide are scarcely soluble, if at all, in water. In spite of this, the oxide is not only active, but also is even transported downwards in coleoptiles, though much less rapidly than hetero-auxin. For when it was applied in lanoline near the tops of coleoptiles on one side, the curves extended for about 5 mm. below the lanoline after 5½ hours at 19° C. Carotene also, as Lazar[1] has shown, though insoluble in water, can produce effects which are distant from the part to which it is applied in plants.

I am indebted to Dr. E. Hope for help and advice concerning the substances tested.

Alkaloids from *Arundo Donax* L.

DONAXINE[1], $C_{11}H_{14}N_2$, is according to von Euler, Erdtman and Hellstrom[2], identical with gramine from certain strains of barley, and according to a paper by Th. Wieland and Chi Yi Hsing[3], to which my attention has just been directed, gramine has the constitution of β-dimethylaminomethyl-indole, $(CH_3)_2NCH_2.C_8H_6N$.

I have for some time been engaged in the study of the alkaloids of *Arundo Donax* L. from the shores of the Mediterranean, and find that, by joint action of alcoholic potassium hydroxide and methyl iodide in the cold, donaxine furnishes tetramethylammonium iodide and a (methoxy methyl)-indole; with ethyl iodide an (ethoxy methyl)-indole results and presumably also dimethyldiethyl ammonium iodide.

Besides donaxine, I have obtained a crystalline alkaloid, $C_{13}H_{16}O_2N_2$, and an amorphous phenolic base; both are indole derivatives. Their relationship to donaxine is being investigated.

Viscosity of Binary Mixtures

IN a recent communication[1], Mr. A. J. A. van der Wyk has presented a new formula for the calculation of viscosity of binary mixtures. I would point out that this problem has already been fully solved in two ways. On the base of thermodynamical considerations, the formula[2]

$$\log \eta = m_1 \log \eta_1 + m_2 \log \eta_2 - \int \frac{q_m}{4{\cdot}57T^2} \quad . \quad . \quad . \quad (1)$$

has been found, where η denotes the viscosity of the mixtures, m_1, η_1, m_2 and η_2 the mole fractions and viscosities of the two components, T the absolute temperature and q_m the molecular heat of solution. The latter may be also considered as the total change in energy caused by the interaction of both components. This change in the energy being rather difficult to determine experimentally, another method[3] based on the association of the molecules has been chosen. It has been found that the simple formula of Arrhenius

$$\log \eta = n_1 \log \eta_1 + n_2 \log \eta_2 \quad . \quad . \quad . \quad (2)$$

gives quite satisfactory results (as must be the case for 'ideal mixtures' where no change in energy takes place), when for the calculation of mole fractions the *physical* molecular weights instead of the *chemical* molecular weights are taken into consideration. If S denotes the number of molecules of the component 2, which in the mixture are associated, the equations

$$n_1 = \frac{m_1}{m_1 + m_2.S} \text{ and } n_2 = \frac{m_2.S}{m_1 + m_2.S} \quad . \quad . \quad . \quad (3)$$

must hold. (In the quoted paper S has been defined as "degree of solvation"; it is better defined as "degree of association".)

It has been shown in the above-mentioned paper that the value S may be calculated from the experimental data in a very simple manner, for it is easy to show that

$$n_1 = \frac{\log \eta - \log \eta_2}{\log \eta_1 - \log \eta_2}.$$

In previous papers the fitness of the above-mentioned formulæ has been shown for quite a number of examples. It will be perhaps sufficient to show it now on the mixture chosen by Mr. van der Wyk, that is, the system benzylbenzoate-toluene. The results calculated on the basis of the equation (2), where for S the value of 1·197 has been found, are shown in the accompanying table:

Viscosity of mixtures of benzylbenzoate and toluene ($S = 1,197$)

m_1	n_1	η obs. (K. and M.)	η calc (equ. (2))	Difference per cent
0	0	0·552	0·552	0
0·2367	0·2785	1·188	1·154	− 2·4
0·4261	0·4762	2·015	1·993	− 1·1
0·6502	0·6948	3·614	3·624	+ 0·3
0·7890	0·8208	5·080	5·104	+ 0·5
0·9002	0·9170	6·660	6·707	+ 0·7
1	1	8·450	8·450	0

The results agree with at least the same accuracy as the data found on the base of the complicated formula of Mr. van der Wyk. Besides, every constant used has a definite physical meaning. Further, with the aid of the equation (1) it is possible to determine also the relationship between viscosity and temperature which is missing in van der Wyk's formula. This relationship shows that the formula of Arrhenius holds better at higher temperatures according to the well-known fact that with increase in temperature 'real' mixtures approach in their properties to the 'ideal' mixtures. The formulæ (1) and (2) also lead to the following conclusions: in the solution of benzylbenzoate in toluene, from each six molecules of the first, four appear in the monomolecular and two in bimolecular form. The heat effect, that is, the total change in the energy of the mixtures, appears in the order 380, 318, 271, 237 and 208 calories, as presented in the table.

These results appear to show the better applicability of my formulæ, as compared with the formula of Mr. A. J. A. van der Wyk.

Temperature Drop Effect in Relation to the Determination of the Molecular Heats of Gases

IT has been shown in a recent paper[1] by one of us (H.S.G.) that, in the absence of convection, the loss of energy (Q) from an electrically heated wire, compensated for end effects and suitably disposed in a gas, is given by

$$\frac{1}{Q} = \frac{\log_e r_2/r_1}{2\pi.K.J.l.\theta} + \frac{A}{p.\theta}\cdot\left\{\frac{\sqrt{T_1}}{r_1} + \frac{\sqrt{T_2}}{r_2}\right\} \quad . \quad . \quad (1)$$

where

$$A = \sqrt{\frac{2\pi.M}{R}}\cdot\frac{1}{2\pi.l}\cdot\frac{(2-a)}{2a.(\beta+1/2)} \quad . \quad . \quad (1a)$$

From the above equation, it is evident that measurements of Q and the corresponding pressure (p) over an appropriate range of pressure enable the values of the thermal conductivity (K) of the gas, and also A, to be calculated. Furthermore, it may be shown that if the observations are continued into the low-pressure region where the gas is rarefied, then the heat transfer is governed by the relation

$$Q = \frac{r_1}{2A}\cdot\frac{(T_1 - T_2).p}{\sqrt{T_2}}\cdot\frac{(2-a)}{J \times 10^7} \quad . \quad . \quad . \quad (2)$$

If the temperatures T_1 and T_2 are maintained constant throughout the whole range of pressure, then assuming independence of the accommodation coefficient a upon pressure, its value can be deduced directly from equations (1a) and (2), and hence $\beta.R$, the molecular heat of the gas, can also be determined by substitution in (1a). We have carried out measurements in the case of hydrogen, and the value of β at 283° abs. was found to be 2·448 and that of the accommodation coefficient 0·31.

It should be noted that for a monatomic gas at ordinary temperatures, β has the value 3/2, and hence by using such a gas in the experimental apparatus a method is provided of checking the indications of the McLeod gauge in the region of rarefied pressure, since equation (2) may now be utilized to calculate the pressure, since β and a are known. In this manner the apparatus can be employed as an absolute low-pressure manometer, and this procedure was successfully adopted in the case of pure helium. Incidental to this calibration of the gauge, the value of the accommodation coefficient obtained in terms of the experimental data and the assumed value of β was found to be 0·35. This result is in excellent agreement with that obtained by Mann[2], and the experiments have thus substantiated the use of equation (1) as an accurate method for the determination of accommodation coefficients.

Origin of Uni-Polar Electrical Conductivity of Carborundum

THE *volume* rectification in carborundum, which is quite independent of any point action, has been observed by many experimenters[1]. An attempt is made here to explain some features of this effect.

When a certain voltage is applied to the carborundum crystal, it causes a displacement of the photo-electrons embedded in the lattice from their positions of equilibrium. When the binding force on the photo-electrons is overcome by the applied field, these photo-electrons are set free. A certain minimum potential difference must then be necessary for any appreciable current to flow in a certain direction in the carborundum crystal. Since all the photo-electrons are not set free at a definite voltage, there must be a certain range of voltage within which all the photo-electrons are released. This will naturally cause a bend in the current-voltage characteristic curve. Beyond the bend, the curve will be a straight line, since the current through the crystal is proportional to $(V - e)$ where V is the applied voltage and e the minimum E.M.F. necessary to liberate the photo-electrons embedded in the crystal lattice. This linearity of the current-voltage curve beyond the bend has been substantiated, when the crystal is held between two electrodes of large contact area. The deviation from linearity is generally found at higher voltages and is due to the Joule heating, which reduces the resistance of the crystal.

Our experiments with carborundum crystal placed between metal electrodes of large contact area have shown that the values of the minimum voltage for any appreciable current to flow are different for the two opposite directions. Thus beyond the bend in the current-voltage curve, in one direction the current is given by

$$i_1 = k_1\,(V - e_1),$$

while the current in the opposite direction is given by

$$i_2 = k_2\,(V - e_2),$$

where e_1 and e_2 are the values of the E.M.F. necessary to liberate the electrons for the two opposite directions, and k_1 and k_2 are constants determining the slopes of the characteristic curve on the positive and the negative sides. The values of the rectification ratio for different voltages as determined from the ratio of the difference in the values of the currents in the two opposite directions to the larger value can then be calculated, provided we know the values of e_1 and e_2, and k_1 and k_2. From one typical current-voltage characteristic curve for the carborundum crystal mounted between electrodes of large contact area, the slopes of the curve beyond the bends are given by

$$k_1 = \tan 83° = 8{\cdot}0 \text{ and } k_2 = \tan 72° = 3{\cdot}0.$$

Putting $e_1 = 0{\cdot}4$ volt and $e_2 = 0{\cdot}8$ volt, we have calculated the values of the rectification ratio for voltages beyond the minimum voltage where the bends appear. The calculated values are shown in the accompanying table side by side with the values obtained from the same characteristic curve for which $k_1 = 8$ and $k_2 = 3$. The observed value for $v = 6$ volts has been made equal to the calculated value of the rectification ratio at that voltage.

Voltage	Rectification ratio	
	observed	calculated
2 volts	0·70	0·71
4 ,,	0·68	0·67
6 ,,	0·65	0·65
8 ,,	0·60	0·64
10 ,,	0·57	0·63

The experimental and the calculated values of the rectification ratio agree well considering that the values given for e_1 and e_2 are only approximate. The current-voltage curve constructed from the calculated data does not, however, fit well with the experimental curve.

That the values of the minimum potential difference are different for the two opposite directions of the current-flow seems theoretically plausible in a crystal having no centre of symmetry.

Some Polarization Data of the Solar Corona

THE polarization of the solar corona was determined from plates obtained in the 1932 and 1934 total solar eclipses. These eclipses were observed under perfect atmospheric conditions. Polarigraphs, equipped with quartz Wollaston prisms and colour filters of narrow transmission ranges, were used. Intensity squares were printed on each corona plate for photometric reduction. The plates were measured with the Hartmann microphotometer of the Lick Observatory and the Zeiss microphotometer of the Physics Department, University of California.

Fig. 1 shows the polarization values obtained at wave-lengths 420, 447, 482, 668 mμ. These curves represent the polarization in the eastern part of the 1934 corona. The curves are the result from the reduction of plates obtained by two polarigraphs. The curve in the green region is of less weight than the other curves because of the use of non-backed plates.

It is very interesting to note that the slope of the polarization curves in the red is much steeper than it is at smaller wave-lengths. The violet curve passes through a maximum and then decreases. The curves intersect at about 4′ distance from the sun's limb. The polarization in the red reaches very considerable values, going up to 57·5 per cent at 6′ distance from the sun's limb.

The results obtained indicate that scattering of sunlight in the corona by free electrons cannot be responsible alone for the light emitted by the corona. Bound electrons seem to be present in the corona, and the corona itself seems to emit unpolarized light.

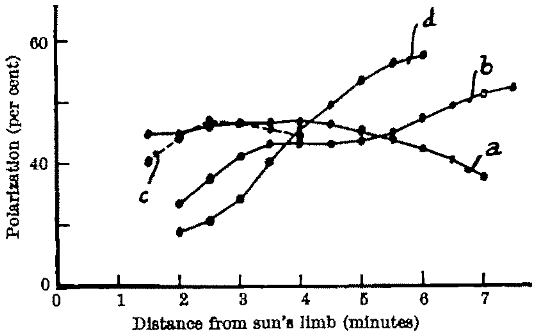

Fig. 1.

POLARIZATION OF THE EASTERN PART OF THE SOLAR CORONA, FEBRUARY 14, 1934.

Curve	Plates	Wratten Filters No.	Maximum transmission
a	Agfa Astro, backed	36	420 mμ
b	Agfa Astro, backed	47	447
c	Eastman I-H	75	482
d	Agfa Superpan, backed	29	668

Detailed results of the reduction will be published later.

Part of the work was supported by grants from the Rumford and Permanent Science Funds of the American Academy of Arts and Sciences. Many friends and institutes helped in carrying through this investigation; see the acknowledgment in the preliminary report[1]. The Imperial Japanese Government furnished the transportation to Laoi Island, and made the observations and work possible there.

Time Lag of the Vacuum Photo-Cell

IN a well-known experiment, Marx and Lichtenecker[1] swept the image of a narrow slit across the cathode of a photo-cell by means of a mirror that could be rotated at speeds up to 170 revolutions per second, and found that the photo-electric current was constant, no matter at what speed the mirror was rotated. The shortest duration of illumination at any point on the cathode was $1{\cdot}46 \times 10^{-7}$ sec. The experiment was taken to mean that the cell had no time lag or period of induction comparable with this interval.

I have recently repeated the experiment with two G.E.C. cells, a *KMV* 6 and a *KV* 6, using a faster mirror and a sharper image, and find that, while the law of proportionality between quantity of light and photo-electric current still holds for the *KMV* 6 cell, there is an appreciable breakdown in the case of the *KV* 6. If the periods of illumination are decreased from $1{\cdot}59 \times 10^{-6}$ sec. to $7{\cdot}4 \times 10^{-8}$ sec., the time required to charge the electrometer to a given potential is increased. My last three determinations give an increase of 0·30 ± 0·50 per cent, 0·70 ± 0·31 per cent, and 0·85 ± 0·59 per cent, the mean of which is 0·62 per cent. If we make the assumption that this increase is due to there being a period of induction before the electrons start to come off, its duration works out at 5×10^{-10} second.

At the highest speed of rotation there is a slight vertical oscillation of the image which puts a limit to the accuracy of the determination, owing to its shifting the light on to a different part of the cathode.

Details of the experiment will be published later.

Primary Oxide Film on Iron

DURING the course of an electron diffraction study of oxide films formed on iron, I have found it rather difficult to obtain surfaces the initial diffraction pattern of which can be attributed to iron alone. In particular, if the surface of a piece of clean Armco or electrolytic iron is abraided by rubbing it lightly over dry 0000 emery paper, the resulting pattern consists of the usual rings of α-iron plus two diffuse rings or bands the mean radii of which correspond to spacings of 2·6 A. and 1·5 A.

The belief that these rings might be due to a thin film of oxide (Fe_3O_4) has been confirmed by a series of experiments with films of electrolytic iron evaporated and condensed *in vacuo* on glass, iron, platinum and quartz surfaces. The evaporation was carried out in the diffraction camera with the receiving surface mounted in the sample holder. Reflection pictures taken immediately after evaporation yielded only iron rings. If, however, the sample is exposed to dry air at room temperature and atmospheric pressure for a brief interval, the resulting diffraction pattern is markedly different. The iron rings are considerably fainter, while two diffuse bands appear in the same positions as found on the abraided iron. In some of the pictures other fainter rings appear which, together with the bands, are in good agreement with the pattern to be expected from a thin film of Fe_3O_4 overlying the iron.

Traces of oxide on evaporated films have been found on pictures taken after brief exposure to air pressures not exceeding 10^{-3} mm. of mercury. Exposures to atmospheric air longer than four minutes produce very little change in the pattern. Heating the specimens in air for 3–7 min. at temperatures of 150°–200° C. is sufficient to cause the disappearance of the iron rings and greatly to strengthen those due to the oxide.

The possibility that a definite orientation relationship exists between the iron and the oxide lattices has been tested by forming thick evaporated films on various surfaces under conditions which yield a high degree of preferred orientation of the individual iron crystals. Such a film all the iron crystals of which have their [111] directions mutually parallel (within 5°) exhibits an equally high degree of preferred orientation of the Fe_3O_4 film after brief exposure to air. The observed orientation relationship is one in which a $[01\sqrt{2}]$ direction of the cubic oxide crystals is parallel to the [111] direction of the iron. This parallelism does not, of course, determine the complete space orientation relationship between the two lattices. It must be pointed out, however, that the observed orientation is exactly satisfied if the Fe_3O_4 cube planes (100) lie parallel to iron cube planes, and the [110] directions in the (100) planes of the oxide are parallel to the [100] directions in the (100) planes of the iron.

Mehl, McCandless and Rhines[1] have found the same orientation relationship existing between "FeO" grown at high temperature on single iron crystals. More recently, Mehl and McCandless[2] have reported that "FeO" grown by reduction on a single magnetite crystal has the same orientation as the underlying Fe_3O_4. In the light of these results, the present experiments can be interpreted by saying that the primary oxide film on iron consists of Fe_3O_4 oriented *as if* "FeO" were formed first and then oxidized to Fe_3O_4. Such is probably not the actual process, because there is no evidence of "FeO" in the diffraction patterns and furthermore it is unstable below about 575° C. As has been pointed out by Mehl and McCandless, there is a striking similarity between the positions of the Fe atoms in the iron lattice and their positions in the "FeO" lattice, and this similarity can be traced through to the Fe_3O_4 lattice when it is oriented as described above.

Electron diffraction pictures of Fe_2O_3 films grown on highly oriented Fe_3O_4 films by heating at 200° C. in air show no trace of orientation. Continuous rings of the randomly orientated Fe_2O_3 crystals appear superimposed on a fading but still well-oriented Fe_3O_4 pattern. Long after the Fe_3O_4 pattern has disappeared, the Fe_2O_3 rings begin to show evidence of a preferred orientation which seems to be independent of the nature and degree of orientation in the underlying layers.

Distortion and Yield Point of Molybdenum

IN a recent communication[1], Dr. E. W. Fell refers to a letter from us[2] and comments on the yield point of molybdenum wires after a certain heat-treatment in hydrogen followed by nitrogen, as shown in Fig. 1 (No. 2) of our letter. He points out that in Fig. 1 (No. 1), which shows the load-extension curve for wires treated in hydrogen only, no such yield point is present, and attributes the difference in the shape of the two curves (that is, No. 1 and No. 2 in our letter) partly to the different heat-treatment affecting the crystal size of the two samples.

While admitting that, in general, the crystal size may have an influence on the yield of the wire, we must point out that, in the particular case dealt with, the crystal sizes of the two samples were exactly identical. Notably the sample No. 2 was pretreated in hydrogen at 1,400° C. for 2 min., and during the second treatment at 1,300° C., which was done for 20 sec. in nitrogen, no further change in the crystal structure occurred at all. Thus it is quite clear that the remarkable yield shown is entirely due to the presence of *nitrogen* sorbed during nitriding at the second treatment.

Incidentally, this can also be demonstrated very convincingly by the following two methods. If nitrided wires treated in the same way as those to which Curve No. 2 of our previous letter relates are reduced in hydrogen, say, at 1,000° C., they revert entirely to a stage which is identical with that represented in Curve No. 1. There is no yield. On the other hand, if wires are heated in the same manner as in that of Curve No. 2, the only difference being that the second treatment at 1,300° C., continued for 20 sec., is carried out in *hydrogen* instead of nitrogen, the resulting wire is exactly like that of Curve No. 1. Again there is no yield.

If, during nitriding, changes in the crystal structure are also taking place, the conditions are somewhat more complicated, and the behaviour of the wire is then dependent on the resulting crystal size as well as on the *quantity* and *distribution* of nitrogen sorbed.

Water and Fat Contents of Tsetse Flies

A CONSIDERABLE amount of work has recently been carried out or is in progress concerning the physiological responses of tsetse flies to environmental conditions. These studies have been largely concerned with the effect on the water and fat content of the flies.

There is a point to which attention may be directed as it has not been taken into consideration in any paper of the above nature which has as yet come to my hand. In estimating the water content, it seems to be the practice to utilize the gross wet and gross dry weights of the flies. It is to be pointed out, however, that the ether soluble 'fat' contains no water, and is very variable in quantity in different circumstances. It is obvious that, with the same quantity of water, the water content, expressed as percentage of the wet weight, will vary inversely with the fat content.

In the course of our work with *Glossina morsitans*, one hundred and fifty unfed flies, killed within two hours of emergence, have furnished a mean water content, based on gross weights, of 70·8 per cent. If the weight of the 'fat', the mean of which is near 1·70 mgm., is subtracted from both wet and dry weights, however, the mean water content is 76·4 per cent. There is practically no difference between the sexes in this connexion.

The distribution of the respective percentage water contents shows the following ranges in round figures:

(1) With 'fat' included: 66–74 per cent.
(2) With 'fat' excluded: 72–79 per cent.

Unfed flies which have been under starvation for any considerable period have naturally consumed a large portion of their fat reserve, and the loss of fat tends to raise the final percentage of water if the latter is reckoned on gross wet and dry weights. On this basis, in fact, it may appear that no significant disturbance of the water balance has taken place during an experiment, whereas if the 'fat' is excluded a significant difference may be revealed.

A single instance will illustrate this point. A group of unfed flies, which had been exposed to certain conditions, returned the following mean figures:

Wet weight	19·6 mgm.
Dry ,,	5·7 mgm.
'Fat' ,,	0·60 mgm.

Using gross weights, the proportion of water is 70·9 per cent, practically the mean of the control. Excluding the 'fat', the proportion of water is 73·2 per cent, which is definitely below the mean of the control calculated on the same basis. Tested by *t*, this result has been found to be statistically significant.

One further point is rather obvious, namely, that, in the case of an insect containing in the first place 70–76 per cent of its weight in water, a considerable loss of actual water is not very conspicuously reflected in the final ratio between wet and dry weights. As this is merely a matter of simple arithmetic, I will not enlarge upon the point beyond remarking that the fact adds importance to relatively small differences in the ratios recorded.

Four Molluscs rarely recorded from the Red Sea

As an example of the way in which the distribution of marine animals is complicated by ecological factors, I quote four species of nudibranch mollusc, all of which are large and conspicuous, and which, though common in Zanzibar, have been rarely recorded from the Red Sea. I have myself only lately seen specimens, though twenty-three out of the last thirty-five years have been spent on this coast:

Asteronotus hemprichi Ehr. One specimen on Sudan coast, 1905; one specimen by Dolfuss, in Gulf of Suez, 1927–29; two here in 1934.

Chromodoris (*Glossodoris*) *annulata* Eliot, fairly large for its genus and so strikingly marked that if seen it could not be missed. Colour white with distinct yellow spots. Mantle border violet, with large rings of the same on the back, one enclosing the rhinophores, the other the gills. None seen until 1934, when two were collected (there is another species here of exactly the same colour except that the characteristic rings on the back are missing. This might be taken for a local variety, but in *C. annulata* the gills are laid horizontally, in the other they are vertical, and kept in motion).

Ceratosoma cornigerum Adams and Reeve. Two specimens by Dolfuss, two here in 1936.

Thordisa crosslandi Eliot, another large form not seen again anywhere until one specimen was taken here this year.

None of these species was found by the Cambridge Suez Canal Expedition.

Colloids and the Biological Effect of Radiation

SOME eight years ago there came to my notice a phenomenon which I now think must have been of the same type as that described in the letter from Dr. F. Ellinger, published in NATURE of December 12, p. 1014.

It was desired to demonstrate by means of a projection microscope the Brownian movement in certain colloidal solutions. Messrs. Zeiss kindly placed at our disposal a projection microscope in which the demonstration substance was subjected to very powerful illumination. It was found that when a colloidal calcium oleate protected by gelatine was placed in the cell, the particles, which showed very active Brownian movement, were rapidly brought to rest in the illuminated area. If the cell was moved slightly, the particles which had been unilluminated were seen to be in active movement, but within some forty seconds all had come to rest. The sol in question contained small quantities of sodium chloride and other electrolytes, and it is suggested that the illumination decreased the stability of the colloid sufficiently for these salts to bring about precipitation.

The phenomenon observed was not due to heating or drying up of the solution, since a water cell was interposed between the source of illumination and the slide, and also when a titan white suspension was substituted for the colloidal calcium oleate the particles remained in active movement during many hours of continuous illumination.

Points from Foregoing Letters

DR. W. B. LEWIS, W. E. Burcham and W. Y. Chang report that α-particles accompany the radioactive disintegration of lithium atoms (mass 8) into beryllium atoms of the same mass, with emission of an electron. These α-particles are attributed to the disintegration of excited ^{8}Be nuclei formed in the above reaction. It appears that the ^{8}Be is always formed in an excited state, and the lowest excess energy is not less than two million electron volts.

Attention is directed by Dr. M. S. Vallarta to a lack of agreement in the observed data concerning the intensity variation of cosmic rays with longitude. Some determinations show a maximum off the West African coast at long. 12° W., in agreement with the theory of Lemaître and Vallarta (assuming the position of the magnetic centre of the earth to be at about long. 160° E., as calculated by Schmidt). Hoerlin and Clay, on the other hand, find a maximum at long. 80° W., in the Pacific Ocean, which would place the magnetic centre at 100° E.

The changes brought about by the yellow oxidation ferment and Warburg's co-ferment consist, according to Prof. J. Kenner, in the removal of a proton and a hydrogen atom associated with an electron. He gives several examples of such reactions and suggests that they may likewise throw light on the function of methyl groups in the lactoflavin molecule in connexion with the activation of vitamin B_2.

The biological activity of corticosteron, a crystalline substance isolated by Reichstein from the cortex of the adrenal gland, is reported upon by a group of investigators from Amsterdam, Oss and Zurich. They find that its curative action upon dogs from which the adrenal glands have been removed, is about 2,000 times that of a standard 'cortin' solution, or 100,000 times that of fresh gland.

Benzoyl oxide and benzoyl peroxide have the property of stimulating growth in the same manner as the growth-hormone 'auxin'—according to experiments by R. Snow. The stimulation of growth was noted after applying the substances, mixed with lanoline, to one side of oat coleoptiles from which the tops had been removed.

Dr. E. L. Lederer compares his equation for the viscosity of binary mixture and that of Arrhenius with the equation recently suggested by A. J. A. van der Wyk, and states that the former two are to be preferred.

An equation for determining the molecular heat of a gas at a known pressure from the loss of energy of an electrically heated wire is given by Prof. H. S. Gregory and R. W. B. Stephens. Alternatively, taking as known the 'molecular' heat of a monatomic gas, it is possible to check the pressure readings of a McLeod gauge in the region of rarefied pressures.

A comparison is given by Dr. S. R. Khastgir of the observed values for the *volume* rectification ratio of carborundum with those calculated by means of a hypothesis which postulates that photo-electrons are set free when a voltage exceeding their binding force is applied. The values of the minimum potential differences needed are different for the two opposite directions of the current flow.

Curves showing the polarization of light of several wave-lengths in the solar corona, from photographs taken during the eclipse of 1934 by means of a specially equipped polarigraph, are given by Dr. W. M. Cohn. The author deduces that both 'bound' and free electrons are present in the solar corona.

The time lag of the vacuum photo-cell has hitherto not been measured, but it is usually assumed to be less than 3×10^{-9} sec. By a refinement of the rotating mirror method, Dr. R. A. Houstoun has managed to measure it for one cell, and finds it to be 5×10^{-10} sec.

Surfaces of pure metallic iron, if they have been at all exposed to air, show the presence of a film of oxide, Fe_3O_4, when analysed by means of the X-ray diffraction method. H. R. Nelson has investigated the orientation of the oxide lattice structure in relation to that of the underlying iron crystals and finds it similar to that which has been observed at higher temperatures in the case of 'FeO'.

While admitting that crystal size may have an influence on the yield point of heat-treated molybdenum wires, as suggested by Dr. E. W. Fell, it is stated by P. Túry and S. Krausz that in the particular case described by them the crystal size of the two samples was identical and the difference in the yield point must be attributed to the presence of nitrogen sorbed during nitriding.

R. W. Jack points out that changes in the fat content of tsetse flies should be allowed for when estimating variations in the 'water balance' of these insects, otherwise significant differences may be overlooked.

Research Items

Palæolithic Portraiture

DR. HERBERT KUHN has assembled all known reproductions of the human form in the Franco-Cantabrian school of palæolithic art with the view of studying how the artist of this school represented himself and his fellow men and women as a type (*Z. Rassenkunde*, 4, 3). These representations, more numerous than is appreciated, fall into three classes: (1) sculptures and reliefs; (2) engravings in which the figure is masked; and (3) engravings in which there is no mask. In (2) and (3) the masked figures predominate, owing to the preoccupation of the period with magic. In (1) statuettes of Aurignacian age in ivory, bone, or other material number fifty-nine from sixteen sites, distributed over an area extending from Italy-Spain-France to Siberia. All but two are female. Of reliefs there are five, all from Laussel, Dordogne. Two of the female figures hold horns in one hand. Of the statuettes of Magdalenian age there are four from four sites, all situated in France. They are of slender type, whereas the Aurignacian statuettes and reliefs are full-fleshed, with the sexual characters strongly marked, thus pointing to connexion with a fertility cult centring in the female. These statuettes, like the masked figures of (2), throw little light on physiognomy in the period. Of the masked figures of (2) there are seventy-one from twenty-four sites. With two exceptions (Klause bei Neuessing, Bavaria, and the Pin Hole Cave, Derbyshire), all the sites are in France. The masks include birds, lion, buck, goat, bison. A number show no features or are unrecognizable. They afford evidence of a cult of magic. The figures without masks (3), from this point of view the most interesting, number nineteen. Of these, eight, including hunting scenes, show no features; but the remaining eleven, with features either in full face or profile, show how palæolithic man saw himself, though at times in so grotesque a form as to suggest caricature. It is to be noted that the head is always short and round. The nose is prominent but broad. A beard is indicated, and the bodies of both sexes are hairy, even on the female breast.

Ætiology of Goitre

GOITRE is a disease, with enlargement, of the thyroid gland, which has a high content of iodine. The results of an investigation by the Committee on Iodine and Thyroid Disease, jointly appointed by the Medical Research Council and the Agricultural Research Council, are contained in a report issued by the Medical Research Council entitled "The Relationship of the Iodine Contents of Water, Milk, and Pasture to the Occurrence of Endemic Goitre in two Districts of England" (Special Rep. Series, No. 217. London: H.M. Stationery Office, 1936. 6*d*. net). Two former studies upon this subject have already been published (Nos. 123 and 154), but revealed discrepancies which made this further work desirable. The accurate determination of minute quantities of iodine met with in the materials examined was carried out by a method devised by Mr. C. O. Harvey, and contained in a report in this series (No. 201). The results embodied in the present report give general confirmation of previous work that environmental deficiency of iodine, as indicated by the iodine content of the local water, is once more shown to be associated with a high incidence of goitre. At the same time, the actual amount of the iodine in the environment is not simply and directly related to the intensity of the incidence of goitre. It is suggested that some factor other than the mere iodine content, such as variations in the availability of the iodine present, may be responsible for the discrepancies met with.

Caddis Flies of India

VERY few species of Trichoptera or caddis flies have been described or collected in India. A recent contribution to this subject is to be found in a paper by Prof. A. B. Martynov, the well-known authority in Leningrad (*Rec. Ind. Mus.*, 37, 93–209; 1935). The paper forms the first part dealing with the suborder Annulipalpia. The material studied by Prof. Martynov was from the Indian Museum, and numbered about 93 species. It is significant that 77 of these species constituted new records for continental India and that 61 of them were previously undescribed. This paper brings the number of Trichoptera-Annulipalpia known from continental India up to about 134 species. From the points of view of zoogeography and ecology, caddis flies are an interesting group. It is very desirable that further investigations should be undertaken, including the larvæ and the exact nature of their habitats. Prof. Martynov's paper, which is very fully illustrated, is one of special importance to students of this order of insects, who will doubtlessly welcome further contributions from the author dealing with the Indian forms.

Corpuscles in Cœlomic Fluids of Invertebrates

A SERIES of four communications by Toshio Ohuye (*Sci. Reports, Tôhoku Imper. Univ.*, Oct. 1936) continues the author's investigations on corpuscles in the cœlomic fluids of invertebrates. The previous papers dealt with a holothurian and an earthworm and the present papers include the examinations of four ascidians, another holothurian, an echinoid and a brachiopod. The papers are well illustrated, and the value of the survey is enhanced because a similar technique is employed throughout and the same person is responsible for the interpretation. In the ascidians and the holothurian, nine different types of corpuscles, and in the echinoid and the brachiopod, six different types are recognized. Some of these corpuscles exhibit considerable variation in the body of the animal and some undergo marked changes when they are removed from the body. Amœboid corpuscles are present in all species examined, and in the echinoid the hyaline amœbocytes may run together to form a plasmodium.

Crossing-over and Chiasmata

THE mechanism of crossing-over is still the subject of much investigation, based on both cytological and genetical data. Dr. K. Mather (*J. Genetics*, 33, No. 2) has applied the chiasmatype theory to the knowledge that crossing-over is not constant per cytological unit distance along the chromosomes, particularly in *Drosophila*, and is able to draw various conclusions from the mathematical discussion. If crossing-over is more frequent at certain points, there must evidently be some localized determining mechanism. The spindle fibre attachment appears to be the site of this mechanism, and in the *V*-shaped chromosomes of *Drosophila* the two arms are known to be independent in their crossing-over. This is less surprising as it is evident that these were originally separate chromosomes. The frequency of crossing-over and chiasma formation in any region is then a function of its distance from the spindle attachment. Owing also to interference, the frequency of crossing-over at any point depends on (1) its distance from the spindle attachment, (2) the length of the chromosome arm. It is concluded that, in *Drosophila*, crossing-over and chiasma formation begin at the spindle attachment and proceed regularly along the arm.

Internal Cork of Apples

'INTERNAL CORK' of apples, which has for some years been a prevalent source of loss in certain areas of New Zealand, has recently been effectively controlled by the injection of boron compounds. H. O. Askew and E. Chittenden (*J. Pom. and Hort. Sci.*, 14, 3, 227; 1936) have found that hydrated borax applied as a top dressing will rapidly increase the boron content of certain soils to a depth of eighteen inches, and is readily absorbed by Jonathan and Dougherty trees. The boron content of apples from a healthy area and free from internal cork was similar to that of fruits from unhealthy soil receiving 100 lb. borax per acre. The treatment was effective in reducing the incidence of internal cork on trees previously affected, and no definite effect on the size or dry weight of the fruits was observed. It was estimated from the boron content of healthy leaves and fruits that the annual boron requirement is approximately 44 gm. per acre, which is amply supplied by a top dressing of 50 lb. of hydrated borax per acre to the soil. Complete control of internal cork was obtained by injecting individual branches of Jonathan and Delicious trees with 0·25 per cent hydrated borax solution. A total quantity of 2·5 gm. was effective, though 15 gm. could be given without injury. Control was also achieved by spraying the trees with 0·1–1 per cent borax solution, and as the addition of lime did not diminish the control, it is suggested that borax may be applied along with routine lime-sulphur sprays.

Cereal Rusts on Incompatible Hosts

DR. THEODORA B. HANES has studied the important problem of what happens when a rust fungus attacks a host upon which it does not normally occur (*Trans. Brit. Mycol. Soc.*, 20, pts. 3 and 4, Nov. 1936). Uredospores of *Puccinia triticina*, *P. glumarum Tritici*, *P. anomala*, *P. coronata* and *P. graminis Secalis* were inoculated upon a wide variety of cereals, and many 'inappropriate hosts' were included. The fungus usually initiated invasion of these unsuitable host plants, but was soon checked by local death of the mesophyll, or even of the stomatal guard cells. Experimental results are set forth in great detail in the paper.

The Refractivity Intercept

THE value of investigations of refractivity in the examination of hydrocarbons and mixtures of hydrocarbons is emphasized in a paper by S. S. Kurtz, jun., and A. L. Ward (*J. Franklin Inst.*, 222, 563; 1936). The authors have used the accurate data available for the isomeric heptanes to examine the additivity of the molecular refractivity, and come to the conclusion that too much is demanded of the classical refractivity equations of Lorenz-Lorentz, Gladstone and Dale, and Eykman. Such equations cannot be expected to give the effect of both variation of temperature and constitution on refractive index and density. A graph of refractive index (n) against density (d) for the homologous series of paraffins confirms the fact that a linear equation expresses the relationship between these two quantities. It is therefore proposed to use the equation $b = n - d/2$ where b is a constant, and is referred to as the refractivity intercept. The latter is characteristic of each homologous series. The refractivity intercept is of greater use in the study of hydrocarbons and hydrocarbon mixtures than the classical refractivity equations, since it is practically independent of boiling point and molecular weight. It is of value in the selection of reliable data concerning the properties of hydrocarbons, and for confirming the structure of new hydrocarbons and establishing their purity. It is of use also in the qualitative analysis of organic liquids. The refractivity intercepts of organic compounds other than hydrocarbons are usually less than unity, whereas hydrocarbons themselves (except in a very few cases) give a value greater than 1·01. In the case of mixtures of hydrocarbons, the intercept may be used to distinguish between saturated cyclic and aromatic hydrocarbons. It is possible, by a graphical method, to analyse quantitatively mixtures containing two or three different types of hydrocarbons. The authors discuss briefly the electronic interpretation of the refractivity intercept.

Development of Radio Receiving Valves

AT a meeting of the Wireless Section of the Institution of Electrical Engineers held on December 2, a paper entitled "Modern Receiving Valves: Design and Manufacture" was presented by Messrs M. Benjamin, C. W. Cosgrove and G. W. Warren of the M.O. Valve Co., Ltd., and the G. E. C. Research Laboratories. This paper discusses the main features in the geometrical design of the types of valve in common use to-day and the various factors, mechanical and chemical, which impose limitations in manufacture. Attention was directed to the fact that the minimum tolerances of the dimensions of the electrode systems must be of the order of one per cent if reasonable similarity of characteristics is to be obtained in the mass production of valves of the same type. The paper includes a brief historical survey of the recent improvements in thermionic emitters and gives details of the precautions necessary in the production of modern highly efficient oxide-coated cathodes and insulated heaters. A brief description of the pumping and activation processes employed in modern manufacture is given, and the main factors affecting the life of a valve are discussed. The authors conclude with some observations on possible future developments of the receiving valve. The reading of the paper was accompanied by demonstrations, illustrating, first the improvement attained in the past five years in making the receiving valve free from microphone noises, and secondly the use of the very small 'acorn' valve for the transmission and reception of telephony on a wave-length of about one metre.

Lobster Research in Norway

DR. ALF DANNEVIG in a recent paper* gives a general review of the lobster industry and lobster culture in Norway. For about twenty years lobsters have been investigated at Flødevigen. Yearly grants have been made for this purpose, and much has been done in studying the lobster in all aspects, especially by fishery statistics, marking experiments and rearing the young to the bottom stage after which they are freed into the sea. The results of these researches have been published in various reports and journals, and here a collected view of the whole problem is given and discussed.

Beginning with the history of the fishery from early times to the present day, the author passes on to details of legislation and shows that there has been a big improvement in the fishery since a size limit and a close season were enforced.

Early researches on lobsters were made by Rathke, G. O. Sars, G. M. Dannevig, Appeløf and Sünd leading to the present author's work, which is chiefly concerned with the rearing of the young. The foundation of our knowledge of the life-history and development was laid down by G. O. Sars, who in 1875 described the post-embryonic development for the first time. The newly hatched larvæ he found in the well of a fishing boat and later collected them in the surface waters of the sea by means of a fine net. In this way he distinguished three larval stages and prophesied that the fourth would probably be on the bottom, which was later found to be true. Even in these early years, Sars advocated summer protection and inspection, both of which have now been in force for some time.

Lobsters were first artificially reared from the egg to the bottom stage by G. M. Dannevig, who showed that the young were very sensitive to salinity and, more especially, to temperature, and also found out the proper way to feed these young. Appelløf did much in the way of biology and studied specially the growth of the lobster and instituted marking experiments. It was on the basis of his work that special rearing experiments were begun in 1912 by O. Sünd, who carried out systematic measurements of lobsters on various parts of the coast. Later the rearing experiments were continued by Alf Dannevig, and are still going on at Flødevigen.

It is shown that males are mature at a length of about 16 cm. at Flødevigen and females at between about 21–23 cm. The eggs are extruded in the summer and development takes about a year, during which time the female keeps the eggs under its abdomen attached to the pleopods. Hatching usually takes place in June or July according to the temperature of the water. A spawning lobster of 23 cm. may have about five thousand eggs. The larval development through three free-swimming stages to the bottom stage takes about fourteen days with favourable conditions and normal summer temperature—about 16–18° C. in the Skagerak.

The natural food of the youngest stages consists of small planktonic animals, but in captivity they thrive on crab meat and ox liver. They seize almost anything but throw it away if not liked. In the rearing experiments in the Isle of Man which have been going on for some years, the larvæ are fed with fresh plankton in which copepods predominate, and they thrive on this. Adult lobsters are not naturally carrion eaters, although they will eat dead fish and crabs. Dannevig has observed that in Nature, sea-urchins, chætopods and thin-shelled mussels take a prominent place as food and he has also found remains of fish. Little is eaten in cold weather, the appetite rising with temperature. No food is taken just before and during the period of shell casting, which takes place usually in late summer and autumn when the reserve food is consumed. During the first few days after casting, the lobster does not eat, but as the new shell hardens the appetite grows and soon is normal again. The best quality lobsters are those with a thick shell which has not been cast for some time; thus the best lobsters are usually those caught in the late winter and spring. In captivity, it is essential to feed the lobsters if they are to be in good condition for eating, otherwise they are watery. Temperature and food are of great importance with regard to shell casting, and lobster growth depends on the casting of the shell.

Growth measurements in captivity compare favourably with those in Nature obtained from marking experiments, and the reared lobster young at Flødevigen grow in much the same way as those reared at Port Erin, Isle of Man. The young at Flødevigen reach a length of about 30 mm. in the first growth period and about 60 mm. in a year, the shell casting, practically speaking, being limited to the time when the temperature is above 10° C.

Marking experiments have shown that there is little sign of wandering far, although the lobsters come into shallow water when the water is warm and go down into the deeper water when it becomes cold, or in stormy weather. On most of the Norwegian coast the wandering is probably limited to about a hundred metres in a horizontal plane. There may then be said to be a stationary stock and, usually, about 44 per cent of the marked lobsters are caught again the year after marking. For example, a hundred lobsters, 19–20 cm., were released in the autumn and 44 were taken again the next autumn, the average size being 22 cm.

The present minimum size is 21 cm., and since it is known that hens are normally not ripe until 22–24 cm., it is clear that raising the minimum size to 22 cm. would save many which will breed the next year, especially as the greater part of the fishermen's present catches consists of those of less than 22 cm. This would also be of advantage eventually to the fishermen, for the catches though smaller would be more valuable. It is calculated that, if the minimum size is raised a centimetre, after two years there will be an increased lobster stock, and this with no lasting expense to the fishery.

Since 1879 there has been a protection period to prevent fishing of lobsters which have just cast their shell. This is from July 15 until the first weekday after September 15, varying slightly in different districts. An earlier protection time in spring would save many breeding lobsters, and extension to later in autumn would bring with it a better quality of fish.

---

*Hummer og Hummerkultur. By Alf Dannevig. (Fiskeridirektoratets Skrifter. Serie Havundersøkelser. Report on Norwegian Fishery and Marine Investigations, 4, No. 12. (Copenhagen: Director of Fisheries, 1936.)

The breeding experiments at Flødevigen are carried on in view of the fact that by increasing the number of young by enclosing a mother lobster, hatching the eggs in captivity and rearing the young to the bottom stage, an increase of lobster stock will be effected, for in this way the larval stages which are the most exposed to dangers are protected for the most susceptible time of their life. The lobsterlings when they have attained the bottom stage are set free into the sea. A technique has now been evolved which is very sure, and one can reckon on an output of 20–40 per cent. It is now possible to bring lobster young from the egg to the bottom stage in so great numbers that it is undoubtedly valuable in increasing the stock. This technique has been described in Dannevig's former paper "The Rearing of Lobster Larvæ at Flødevigen" (1928). The technique being established, it is now only a question of how cheaply the whole of the rearing and transport can be effected. There is every ground for believing that it is possible to bring working expenses of production down to a fractional part of the present amount. The plans for the immediate future include still further research in those areas where the young are released. So far, the rearing experiments have prospered. Important results should follow these successes.

Petroleum and Petroleum Products

THE group of papers on conservation of petroleum and natural gas given at the third World Power Conference forms the subject of a report by H. C. Fowler (Section IV, Paper No. 12). Mr. Fowler stressed the principle enunciated by Sir John Cadman that petroleum should not be produced without adequate need, having regard to the vital part played by crude petroleum in the life of civilized communities to-day, and the view held by technicians that resources of crude petroleum are not unlimited. The problem of conservation presents a different aspect in each oil-producing country, and it is difficult to assess it from the point of view of world resources. In the case of the United States of America, the problem is unique and the ultimate policy adopted there will probably have a greater influence on the world petroleum industry as a whole than that of all other oil-producing countries combined.

Before effective measures for world conservation can be adopted, however, there are certain preliminary investigations to be made. The extent and character of waste production in countries having relatively large portions of known oil resources should be determined and note taken of methods employed to conserve resources under specific conditions. In those countries which depend chiefly on imported supplies of oil, the problem should be regarded from the point of view of conservation of utilization. Further, organization of the industry in different countries should be surveyed from the point of view of the effect of property laws, State regulations, etc. Finally, the uses of petroleum should in every case be justified or otherwise, and decisions on this point taken only with full cognisance of all possible substitutes for petroleum and a knowledge of their specific uses. These and other economic factors which are bound to affect utilization and conservation of petroleum should be carefully weighed before judgment is passed on the whole problem of how best to use or conserve this commodity, which now seems indispensable to modern industrial life, but is at the same time believed to be capable of exhaustion.

In his general report (Section II, Paper No. 6) on papers submitted at the Conference on the organization of the production, transportation and distribution of natural and manufactured gas, E. R. Weaver directed attention to the marked contrast between European and American practices within the gas industry. The contrast is chiefly attributable to the greater abundance and variety of fuels obtainable in America, and to different legal and financial factors within the industry. Moreover, in practically every European country, distribution of adequate gas supplies is undertaken by public bodies, whereas in the United States of America public interest is for the most part not represented on the boards and councils of gas concerns. Large holding companies, therefore, compete with each other for areas of supply and are not responsible for their policies to any higher authority. This fact cannot be said to further ultimate national conservation of this commodity in America.

In the case of European countries, a strikingly similar development of the gas industry appears to have taken place in each of them, and such differences as exist are rather differences in stages of development than fundamental dissimilarities. Germany is at present pursuing an advanced policy of consolidation, the professed ideal being delivery of gas to every station at every moment as economically as possible, and also at the same time withdrawal from each producing unit of an allotted quota. To achieve this, not only daily but also hourly load of every pipe has to be calculated and attention given to weather reports and other factors likely to influence gas sales. The question now being debated by technicians is whether fundamental conditions exist in other European countries which will prohibit a similar national programme of gas economy to that aimed at by Germany.

E. B. Swanson gave a general report (Section II, Paper No. 5) on papers in connexion with present-day organization of the petroleum industry. The industry may be said to comprise five structural components: exploration, production, transportation, manufacturing and distribution. The degree of economic stability attainable by an individual country or company is dependent largely upon the extent to which it is possible for it to enter into all five branches of the industry's activities. Papers descriptive of the organization of the petroleum industry in the Argentine, Austria, Canada, China, France, Germany, Great Britain, Hungary, Poland and the United States, substantiate this fact, and at the same time facilitate classification of these countries into four categories: producer; producer-refiner-marketer; purchaser-refiner-marketer; and purchaser-marketer.

The ultimate aim of each country is to engage in all branches of the industry and to attain a balanced degree of activity in each branch.

Several factors, however, determine the status of individual countries and/or units within the industry. The most important of these are the extent to which the indigenous supply of crude petroleum is capable of fulfilling the demand for petroleum products within a country; problems of general industrial organization and the extent and influence of governmental control or assistance. In turn, the degree to which governmental influence is exerted or withheld is based on the particular growth of the industry within each country. Far-reaching governmental control and stringent legislation will be found to operate in those countries where there has arisen progressive lack of balance between indigenous supply and home demand, lack of stabilization of markets through non-participation of lesser units, or other economic maladjustments.

The Bushman Skull

IN the course of a discussion of the significance of the Bushman skull (*Soölogiese Navorsing v. die Nas. Mus., Bloemfontein*, 1, 3–4), Dr. T. F. Dreyer contends that the genus *Homo* at a very early date evolved along three independent lines—Neanderthal, the Eurasian and the Bushman. The Bushman, in the smallness and orthognathism of the face, the steepness of the forehead, and the flatness of the dorsal profile, shows features, in which it resembles the juvenile skull. It is here suggested that this fœtalization' (Bolk) is not due to an adult retention of juvenile features, but is a precocious assumption of the adult. This explains the fact that a Bushman baby of about twelve months is already a Bushman, and differs distinctly from the babies of other races, as does the adult Bushman from other adults. This difference is thus due to the projection of adult features into the earlier ontogenetic stages.

The typical orthognathism of the Bushman skull, after a period of prognathism which lasts for some months after birth, is extreme up to six years and then is less pronounced in maturity. This is a result of two growth processes, the peak of jaw formation falling within the fœtal period, while the upper face, correlated with the growth of the base of the brain, grows more rapidly during the first six years after birth. The cranial form, with characteristic bulging of the forehead and flatness of the dorsal profile, is due to the differential growth of the roof and floor of the brain; there being a lack of growth of the anterior end of the base, while the roof grows very slowly during fœtal life, very rapidly during the first two years after birth, and then keeps pace with the floor of the brain until maturity is reached.

Modern miscegenation with Bantu produces a small brain and a long face (Baralong), but early crosses of Bushman with a Hottentot-like race (Matjes River) produced a large brain with a small face. In both cases the proximate cause appears to be a disturbance in the functioning of the pituitary gland. The sella turcica in the Bush-Bantu is abnormally large—the first case recorded of hypertrophy of the pituitary in an African—while in Bush skulls the sella turcica is abnormally small.

Hybridization with the Bushman would thus seem to set up a disturbance of hormonic control, with the result that one or other set of racial characters becomes exaggerated. It remains to be determined whether the differences between the Bushman and other groups of *Homo sapiens* are of such a degree of importance that most important physiological disturbances result from hybridization, and are of sufficient weight to demand the separation of the race from *H. sapiens* as a distinct species.

Work of the Rothamsted Experimental Station

IN studying the annual report for 1935 of the Rothamsted Experimental Station*, it is impossible not to be impressed by the number and value of the experiments carried out at this institution in co-operation with various bodies and individuals. If the British farmer and his trading associates are averse to co-operation in commerce, they have not proved to be so in the field of research directed from Rothamsted. One of the fruits of bringing together producer and expert buyer has been progress in the direction of understanding 'quality', as applied to some agricultural products.

A series of fertilizer experiments, carried out with the help of the sugar-beet factories, and planned at the Statistical Department at Rothamsted, has the object of putting the manuring of this crop on a sound and more accurate basis. Trials carried out in Great Britain indicate that this crop does not give the response to various manures that might be expected from Continental experience. In the trials directed from Rothamsted, not only is the effect of fertilizers carefully assessed, but also an elaborate examination of the soil is in progress, in order to correlate soil properties and fertilizer responses. This crop is also the subject of trials at Rothamsted and Woburn, arranged under the ægis of the Ministry of Agriculture and of the sugar-beet factories. These trials are designed to measure the effects of spacing, and of sulphate of ammonia applied at different spacings; the results at both centres indicate that nitrogen produces a greater effect in the narrower rows.

Useful information was gathered from conferences of growers of malting barley; these took the form of exhibitions of samples sent from various parts of the country, and valued by the Barley Valuation Committee of the Institute of Brewing. One of the most interesting facts gleaned is that the results of the experiments made by Rothamsted in the last ten years on the manuring of barley have passed into practice; these results indicated that barley is not a starvation crop, and that, provided the danger of lodging is kept in mind, the crop repays manuring.

---

* Rothamsted Experimental Station: Lawes Agricultural Trust. Report for 1935. Pp. 279. (Harpenden: Rothamsted Experimental Station, 1936) 2*s*. 6*d*.

The expanding acreage of vegetable crops grown in Great Britain is reflected in the increasing attention given them in the Rothamsted scheme of experiments. The expansion in this branch of work was made possible by the investigation into the value of dried poultry manure, put in hand by the Ministry of Agriculture and controlled from Rothamsted. Although the standard errors proved to be rather higher than the average of large-scale root-crop trials, a number of statistically significant fertilizer effects were found for some crops. More work was done on Brussels sprouts than on other crops. Comparing poultry manure with sulphate of ammonia providing the same amounts of nitrogen, the results indicate that, in the more favourable growing season of 1935, as compared with 1934, sulphate of ammonia proved more effective. Another interesting feature is that the manurial responses showed up more in the first pickings—an important consideration in the marketing of this crop.

The report has also something of interest for hill farmers. In the Bacteriological Department, the work on clover organisms continues, and it appears that the soils of certain hill districts contain harmful strains that do not themselves benefit the clover plant, and also prevent most beneficial strains from forming nodules. Some beneficial strains, however, can overcome the harmful effects of the bad strains, and enable the plant to make normal growth. Promising results have been obtained from experiments on the inoculation of these beneficial strains into soils containing the harmful ones.

The Report includes a review by Dr. W. Brenchley of thirty years' work of the Botanical Department (1906–36). The problems tackled by this Department have been many and varied. The work on boron in relation to plant growth is one of many interesting landmarks in this survey. A chance observation directed attention to the possibility that this element might be essential for plant growth, and it was established conclusively by later work that boron is essential for the growth of many plants, the meristematic tissues being affected in its absence. Dr. Brenchley is perhaps best known in the agricultural world for her researches on weed eradication, work that demanded a number of surveys to ascertain how far weed species, or groups of these, are associated with particular soils or crops.

The survey concludes with an account of the work on the Park grass plots, in which various aspects of grassland management have been studied, such as the influence of season and manuring upon the botanical composition of the herbage from year to year.

Separation of Isotopes

AN interesting report by G. Champetier (*Bull. Soc. Chim.*, (5), 3, 1701; 1936) deals with the separation of the isotopic forms of elements.

The proportion of the isotopes in an isotopic mixture is very variable. In hydrogen, the atomic ratio is $^{3}H : {}^{2}H : {}^{1}H = 7 \times 10^{-10} : 1/5750 : 1$; bromine is a mixture of approximately equal parts of ^{79}Br and ^{81}Br. Apart from the well-known case of the isotopes of lead produced by the radioactive changes of uranium (^{206}Pb) and thorium (^{208}Pb), slight differences in the atomic weights of different specimens of natural elements have been found. A difference of 0·000108 in atomic weight between atmospheric oxygen and oxygen from the water of Lake Michigan has been reported. Small differences in density of water from the surface and from the depths of the sea in various localities are probably due to separation of light and heavy water by gravity. The first quantities of water collected in rain are heavier than the following, whilst snow and glacier water is lighter than ordinary water. These separations are due to differences in vapour pressure and melting point. Water from the wood or dry leaves of a tree is heavier than normal water. All these differences are very slight.

The artificial separation of isotopes has been achieved in various ways. Neon has been separated by fractional diffusion; mercury, zinc, potassium and chlorine (as hydrochloric acid) by distillation at very low pressure; minute quantities of the lithium isotopes, ^{6}Li and ^{7}Li, and more appreciable amounts of the potassium isotope, ^{39}K, by the mass-spectrograph; and neon, hydrogen, water, ammonia, carbon tetrachloride and oxygen by fractional distillation.

The diffusion method gives better results. If x_0 and y_0 are the volumes of the two constituents in the original mixture, and x and y the volumes remaining after diffusion, the enrichment coefficient $r = \frac{y}{y_0} \div \frac{x}{x_0}$ is related to the isotopic masses m_1 and m_2 by the equation

$$r = a\sqrt{V_0/V}$$

where $a = (m_1 + m_2)/(m_1 - m_2)$; $V_0 = x_0 + y_0$; $V = x + y$. The values of a for HD and H_2 is 5, for neon 21, and for $^{18}O^{16}O$ and $^{16}O^{16}O$, 33. The diffusion method has been particularly used by Hertz, who has used batteries of porous clay tubes in series, and also by diffusion into mercury vapour of the pumps circulating the gas. In the first method, pure ^{20}Ne has been obtained, and in 8 hours 1 c.c. of pure D_2 from a mixture containing only 1 in 1000 of D_2. Recently, a partial separation of the carbon isotopes ^{12}C and ^{13}C has been achieved by diffusion of methane. Diffusion of hydrogen and deuterium through heated palladium has also been used.

The electrolytic method is the one most successfully used in the separation of hydrogen and deuterium from water. A slight separation of the oxygen isotopes is also effected, but it has been calculated that, to obtain 1 c.c. of $H_2{}^{18}O$ by this process, it would be necessary to electrolyse more water than is found on the surface of the earth. In an attempt to separate the tritium isotope, ^{3}H, from water, 75 tons of water have been reduced to 0·5 c.c., when the ^3H content rose from 7×10^{-10} to 7×10^{-6}.

Separation of isotopes has also been achieved by chemical means. These generally make use of the so-called exchange reactions, of which the following are typical:

$$NH_3 + HOD \rightleftharpoons NH_2D + H_2O ;$$
$$2H_2{}^{18}O + C^{16}O_2 \rightleftharpoons 2H_2{}^{16}O + C^{18}O_2.$$

The photochemical method is probably capable of extension. Phosgene, $COCl_2$, containing the chlorine isotopes 35 and 37, is exposed to light, when the molecules containing only ^{35}Cl are preferentially decomposed (in presence of a trace of iodine). The free chlorine is absorbed by mercury and has an atomic weight lower than normal. Preferential photochemical oxidation of the mercury isotopes has also been achieved.

University Events

BIRMINGHAM.—The degree of D.Sc. has been conferred on the following: Donald Parkinson (geology) for papers on "The Faunal Succession in the Carboniferous Limestone and Bowland Shales at Clitheroe and Pendle Hill", "The Carboniferous Succession in the Slaidburn District of Yorkshire", and other papers published in the *Quarterly Journal of the Geological Society* and elsewhere; Robert Anthony Robinson (chemistry) for "Investigations on the Thermodynamic Properties of Aqueous Solutions of Electrolytes" published in the *Transactions of the Faraday Society* and for other papers; Horace Augustus Thomas (electrical engineering) for papers on the "Frequency Stabilisation of Valve Oscillators" and "Developments in Rotating Radio Beacon Transmitters and Receivers", published in the *Journal of the Institution of Electrical Engineers*.

CAMBRIDGE.—The Clerk Maxwell scholarship has been awarded to E. Bretscher of Fitzwilliam House.

DR. SIMON FLEXNER, emeritus director of the Rockefeller Institute of Medical Research, has been appointed Eastman visiting professor in the University of Oxford for the academic year 1937–38. The professorship was founded by the late George Eastman of Rochester, U.S.A., to provide for scholars in American universities to go to Oxford as visiting professors for terms of one to five years.

THE Rhodes Trust has issued a statement for 1935–36 showing the distribution of the Rhodes scholars (95 from the British Empire, 90 from the United States and 5 from Germany) among the various subjects (either in the final honour schools or for research degrees) chosen by them. It shows a large majority under the headings natural science and medicine (62), philosophy, politics and economics (41), and jurisprudence and B.C.L. (32). Next come modern history (14), English (13), mathematics (8), Litt. Hum. (7), economics (6), geography (3), modern languages (2), theology (1) and education (1). Of the 16 who obtained honours in philosophy, politics, and economics, 12 were from the United States, 2 from Canada and 2 from Africa.

Science News a Century Ago

J. D. Forbes's Work on Terrestrial Magnetism

ON January 3, 1837, in a letter to Arago, J. D. Forbes said: "I write to mention some results respecting terrestrial magnetism at which I have lately arrived. In 1832 I made an extensive series of experiments with Hansteen's Intensity Apparatus in the Alps, and in 1835 in the Pyrenees. One principal object was to ascertain the influence of heights. I doubt extremely whether any decided result can be drawn from preceding observations. . . . Those of M. Kuppfer seem to be of little value. They were not made at the summit of the Caucasus. . . . I have referred the positions of my stations in the Alps and Pyrenees to the three co-ordinates of latitude, longitude, and height, and deduced the influence of each. . . . I have in the first instance confined my calculation to horizontal intensities. From three different series of observations, made with two needles, I find always a negative co-efficient of the height, indicating, at a mean, a diminution of ·001 of horizontal intensity for 3,000 feet of vertical ascent. If, as Humboldt states, the dip diminishes in ascending, the diminution of total intensity will be somewhat greater. You will judge of the extent of the inductions upon which this is founded when I mention that the sum of the heights to which I have carried Hansteen's apparatus exceeds 160,000 feet, or thirty vertical miles, twelve *lieues*".

Airy at Greenwich Observatory

IN his review of the events of 1837, Airy in his autobiography said: "My connection with Cambridge Observatory was not yet finished. I had determined that I would not leave a figure to be computed by my successor. In October [1836] I had (at my private expense) set Mr. Glaisher to work on reducing the observations of Sun, Moon, and Planets made in 1833, 1834 and 1835; and subsequently had the calculations examined by M. Hartnup. This employed me at times through 1837. I state here, once for all, that every calculation or other work in reference to the Cambridge Observatory, in this and subsequent years, was done at my private expense".

"On Jan. 3rd," Airy wrote, "I gave notice to the Admiralty that I had finished the computations of Groombridge's Catalogue, and was ready to print. The printing was authorized and proceeded (the introduction was finished on Nov. 22nd) but the book was not quite ready till the beginning of 1838". For furthering the magnetical work at Greenwich more ground was necessary. When the Visitors met in 1836, a suitable site was chosen and in 1837 "on Jan. 3 I was informed unofficially by Mr. Wood (Admiralty Secretary) that the addition of the Magnetic Ground was sanctioned".

Among other entries relating to 1837 is that in which Airy says "In the month of July the Admiralty wished for my political assistance in a Greenwich election, but I refused to give any".

Botany of Battersea Fields

AT a meeting of the Botanical Society held on January 5, 1837, a communication was read by the curator, Mr. Daniel Cooper, author of "Botanical Rambles within Thirty Miles of London", on the distribution of the localities of wild plants in Battersea Fields. It was accompanied by a map of the district to a scale of 2 feet to the mile, with the locality of the plants shown. Mr. Cooper said that the Battersea Fields had been for years past famous for the profuse supply of specimens of interest to the naturalist, particularly to the botanist. Of the 104 natural orders of British flowering plants mentioned in Dr. Lindley's first edition of his synopsis of the "British Flora", "61 are found in this locality; of the 503 genera, 214 are here distributed; lastly, out of the 1500 estimated species of British flowering plants 406 are here dispersed".

Cooper, who was trained in medicine and became an assistant in the zoological department of the British Museum, died at Leeds on November 24, 1842, at the early age of twenty-five years.

A Stephenson Locomotive in Russia

QUOTING from a letter from St. Petersburg dated December 14, 1836, *The Times* of January 6, 1837, said: "The locomotive engine made by Mr. Stephenson of Newcastle-upon-Tyne was tried on the 11th on the iron railroad from Paulowsk to Kouzmino. Notwithstanding the extreme severity of the weather a crowd assembled to witness the experiment, the interest of which was increased by the fact that an apparatus of four brushes had been affixed to the engine, for the purpose of clearing the snow from the rails; the apparatus succeeded completely. The engine drew eight waggons or carriages, containing 256 persons, from Paulowsk to Kouzmino, a distance of 7 wersts, or a full German league in 17 minutes, and returned in the same time. . . . On this occasion birchwood was used as fuel, in order to prove that coal is not indispensable, although there is no doubt that with coal the velocity would be considerably increased".

Societies and Academies

Edinburgh

Royal Society, December 7.

A. M. Hain: Microphthalmia and other eye-defects throughout fourteen generations of albino rats. The affected rats were healthy, vigorous animals, but the female parent of such rats rarely littered again after giving birth to young with defective eyes. Analyses of selected matings showed that, out of a total of 154 defectives, only 8 were born to defective parents, whereas 132 were born to normal parents with defective antecedents. The mode of inheritance was not straightforward; the data are consistent with the existence of a dominant factor with a poor expression which is conditioned by genetic and physiological modifiers.

H. P. Donald and Miss Rowena Lamy: Ovarian rhythm in *Drosophila*. In *Drosophila pseudo-obscura* an ovarian rhythm is present which is characterized by the ripening and laying of eggs in batches with long periods of rest between bursts of oviposition. The form of the rhythm varies according to age and to absolute fecundity as measured over a period of days. In *D. funebris* and *D. melanogaster* no rhythm has been observed, but in the former there is a distinct tendency to lay during the daytime. Examination of the ovaries provided consistent results.

R. A. Sampson: Studies in clocks and timekeeping. (6) The arc equation. In 1930, the clock "Shortt No. 4" showed evidence of the mutual effect of variations of pressure, arc and rate. Observation revealed that the effect of pressure upon arc increased as pressure diminished; ultimately a balance obtained, and further reduction of pressure made the clock go slower in place of faster. The experimental question of the effect of arc upon rate is indeterminate at any one mean pressure. At full exhaustion, the whole circular error should presumably appear. Investigation is made whether it appears full at other pressures, with comparison with the experiments of other authorities.

J. Small and I. K. Johnston: Quantitative evolution in Compositæ. The frequency distribution of generic sizes in Compositæ agrees reasonably well with the calculated frequency distribution, using Yule's formulæ. The ages in doubling-periods for the subtribes within tribes show a clear seriation with previously suggested order of origin. The *Dp*-ages of both tribes and subtribes show a complete seriation with suggested times of origin when averages are taken for each of the geological periods concerned, and this seriation extends to the subdivisions of both Pliocene and Miocene.

National Museums of Natural History

AT the present day most States possess their national museums, in which are exhibited long ranges of animals, plants, fossils and rocks. Many of their larger cities support their own local museums, regarding them as centres of culture and of education. Such smaller museums cater for a local population, and for the most part their exhibits centre round their own localities. They are generally connected with the local education authority and with a local university if such exists. The interests of national museums, on the other hand, extend farther afield. They usually attempt to show a world range in their exhibits, while displaying with especial care the organisms of their country. They thus are associated with the higher education of their nation, specialists in the biological sciences usually passing some part of their student days in study within their walls.

This association of natural history museums and teaching is well seen in the study of their foundation and history. Sir Richard Owen, in a Royal Institution lecture in 1862 "On the Extent and Aims of a National Museum of Natural History", after discussing the foundation by Prof. Louis Agassiz of the Museum of Comparative Zoology at Cambridge, Massachusetts, went on to remark (p. 110) that "the instances of the most rapid advance and perfection of Natural History Museums have all been associated with the fact of their curatorships by professors notable for their successful public teachings of the science; as, for example, the Botanical Museum at Upsal, under Linnæus; the Anatomical and Palæontological Collections at Paris, under Cuvier; the Zoological Collections at Paris, under Geoffroy St. Hilaire, Lamarck and Latreille". Sir Richard Owen, whose advocacy extending over twenty years induced the Government in 1877 to vote £70,000 for the erection of the Natural History Museum, South Kensington, himself lectured for a long period at the Royal College of Surgeons, where the professor is by the statutes required to give annually not less than twenty-four lectures, a combination of the functions of professor and curator which he urged "on every suitable opportunity".

Owen made the Natural History Museum a national institution, and he was succeeded by Sir W. H. Flower, who had been Hunterian professor at the Royal College of Surgeons, while two of the subsequent four directors had previously been teachers in universities. The reason is obvious; such teaching officers have necessarily to keep themselves abreast of the most recent developments of their science—and such developments constitute the section in any museum most interesting to the public. An art museum may leave very many exhibits on display permanently; indeed, only altering them when a better piece by the same artist is obtained. In contrast a science museum, except in historical exhibits, must be for ever changing as its science evolves. It may be in advance of its public where the perspicacity of its director makes this possible, but it must never lag far behind or it will be deemed to be a collection of 'dry bones', worthy of a visit perchance but useless for study.

In national museums there is, however, a secondary function to which we more particularly wish to refer. Advances in biological science are often founded on definite specimens of animals and plants, living or fossil. Those specimens are the authority upon which the advance is based, and, as at once acquiring historical importance, should be preserved. Universities and teaching institutions may attend to this, but their changing personnel with new interests too frequently neglect or disperse the material on which their predecessors' work was founded. Clearly the only place for a permanent historical record, representing the advances of the nation, is in the national museum, the bias of which is preservative.

Often such research material consists of long series of animals or plants, systematic or taxonomic collections, as they are termed. The species is the unit in biology, because it is something definite in structure, to which a name can be given with a full meaning thereby implied. Besides its exhibition series, a great museum collects and preserves examples of as many species of animals and plants as it can obtain, so that the inquirer has the inestimable advantage of seeing the concrete form rather than being dependent on written description. There are millions of species, and a museum sets out to contain as many type specimens, both male and female, as there are species, or as many as it can secure.

The museum is thus a 'library' of species brought together so that the basal accuracy of science can be maintained. But single specimens of species are not sufficient. There must be added a series of specimens illustrative of such variations as are induced by climate, nutrition and other external factors. These for the same species fluctuate in different countries, and the species from each may have to be preserved. The museum curator is a cataloguer and, so great are the number of species and the diversity of phyla of animals and plants, that he may spend all his life in becoming a specialist in one narrow groove. He may be extraordinarily capable in his own line, but he is in danger of thinking of his organisms as dead material, which is to be merely catalogued on its anatomies. This may be corrected by sending him into the field to collect and study, as is done by most museums, greatly to their and his advantage. Yet withal, he gets little opportunity of thinking of his creatures as essential entities in that single realm of Nature, for which the museum, both in its exhibitions and in research, must stand.

Ideally there should be one great clearing house of species for all countries, but this, with the rivalries of nations and the delays involved by distance, is impossible to attain. Museums try to preserve as many of the specimens used for the original descriptions of species as may be obtained —'types' as they are termed. In practice, museum specialists compare specimens with these original types, and these, if proved by a competent specialist to be the same species, become almost as useful as 'types', the possession of which is only of importance should doubts arise. Each continent has its own museums, many specializing in its fauna and flora, but it is only in Europe and the United States where there are museums—and they are few in number—which try to embrace all species of all countries and which alone can act as efficient clearing houses. Such necessarily great collections can only be developed on national lines, being quite beyond the means of private institutions. This is well illustrated in the British Museum (Natural History) at South Kensington, which employs more than fifty scientific officers mainly in conserving and cataloguing its immense cosmopolitan collections.

Of course naturalists can do without museums in countries where their more happily situated neighbours can give them hospitality in such. Thus difficulties and dangers to science need scarcely be felt in Europe or North America In South America the accurate determination of the flora and fauna is generally impossible since there are not the necessary central collections. South Africa depends partially on Cape Town, while collections from the tropical and northern parts must mostly be referred to London, Berlin or Paris. At present, London has larger collections from their localities than either the Indian or Australian museums, the sole institutions representative of the life of their continents. Here are four museums founded on British culture, of which those of London and Calcutta are in heavy centres of population, while those of Sydney and Cape Town may well one day represent nations in importance akin to the United States.

What relationship, beyond the ordinary courtesies of friendship, exists between these institutions ? We know of no such ties, and we wonder whether the interests of science in our Commonwealth of Nations would not be best served by attempting to develop such links. A free interchange of co-types could do much. The same specialist could determine the species of his group from all the four regions with a distribution of the named specimens to all. But more is wanted, for the taxonomists in all must have the same methods and ideas as to species in their work, and this can be secured by the periodical interchange of members of their staffs. Most are in the employment of their States and would welcome such an interchange. Is it not worth while for their Governments to regularize and encourage such visits, the effects of which may well extend far beyond the limits of pure science ?

The Theory of Dimensions

The Theory of Dimensions and its Application for Engineers
By Dr. F. W. Lanchester. Pp. xxiv+314. (London: Crosby Lockwood and Son, Ltd., 1936.) 12*s.* 6*d.* net.

"THE first business of an author," says Dr. Lanchester in the preface, "is to state clearly the object of his work. . . . This book is written with the primary object of helping the young engineer to acquire a sound knowledge of dimensional theory, a subject which he can no longer afford to ignore." Although the subject forms a part of the curriculum of the engineering courses in all universities, the author maintains that subversive doctrines are being taught, and one of the avowed objects of the book is "to extirpate heresy of this kind", a job which he sets about with evident zest.

Of the 314 pages, about a hundred are devoted to tables of physical constants of the atmosphere, water, steel, fuels, etc., weights and measures, and although they contain much useful information, many of these chapters make little or no mention of dimensions. The rest of the book may be divided into two parts, mechanical and electrical. In the former, the author is evidently on his native heath; he hits out with no uncertain aim and speaks with an authoritative air. In the latter he is admittedly an explorer, feeling his way, asking directions from others, and quoting their opinions. As he says, "No attempt is made in the present work to decide between one system and another; the author has endeavoured to keep an open mind—only he declines to subscribe to any system that does not conform to his axiom," the axiom being that any one physical entity cannot have assigned to it more than one dimensional expression. In the preface he makes the somewhat enigmatic statement that "the fundamental dimensions recognised by physicists are (1) length, (2) mass, (3) time. There are really no others." It is not quite clear whether this is intended to mean that if physicists did recognize any other they would be sinning against a Lanchester axiom, but this doubt is dispelled when, with reference to Everett's statement that the choice of fundamentals is a matter of convenience, he says that it may be so, but, if true, is of little more than academic interest.

After showing that the entity and its dimensions are not one and the same, and that even the concept of velocity is not necessarily associated with length and time, but only becomes so by our definitions and methods of measurement, the author launches into an attack on the 'slug', a unit of mass introduced about fifty years ago by Prof. Perry and apparently still used by some misguided folk. A five-page appendix on the same subject is a sermon on the text, "the evil that men do lives after them".

The chapters dealing with the application of dimensional theory to a large variety of mechanical problems are excellent. In discussing thermal entities, the author regards entropy as a dimensionless numeric, whereas Kaye and Laby give it dimensions; temperature is regarded as having dimensions L^2/T^2, and the heat imparted to a mass to raise its temperature becomes ML^2/T^2, the dimensions of energy. This matter is also discussed in an appendix.

Only forty pages of the book, excluding appendixes, are devoted to electric and magnetic dimensions, but the whole of Rücker's paper on "The Suppressed Dimensions of Physical Quantities" is reprinted as an appendix, as is also FitzGerald's paper on "The Dimensions of Electromagnetic Units", and a paper by Sir J. B. Henderson on "Fundamental Units in Electrical Science".

It is on p. 104 that the author leaves his native element and enters the electromagnetic world. In his opening sentence he says, "Electrical entities depend upon the three fundamentals *L*, *M*, and *T*, as do other derived physical entities discussed in the preceding chapters". It would have been more explanatory of the history of the subject if he had said that they may be made to appear to depend upon *L*, *M*, and *T*, by making certain arbitrary assumptions about which scientific workers have been squabbling for the last fifty years. The same is true of the subsequent statement that "it is agreed by all authorities that electrostatic units and electromagnetic units have different dimensional values although the entities represented may be the same". Is it not that they are made to appear to have different dimensional values by the adoption of different arbitrary assumptions? The electrostatic units of inductance or capacitance may differ largely in magnitude from the corresponding electromagnetic units, but they cannot really have different dimensional values.

Although the author expresses strong disapproval of the unit pole, he has not been bold enough to free himself entirely from it. Much of the confusion and uncertainty which pervade the electric and magnetic units is due to the fact that the classical system is based in part upon an ill-defined unreality, namely, the pole strength of a permanent magnet. If we assume that ferro-, para-, and dia-magnetism are all due to the orbital movements of electrons superposing their effects upon the externally applied magnetomotive force, we are justified in regarding all magnetic phenomena as electromagnetic, and as being manifested in 'non-magnetic' space. In iron, the value of H is enormously increased by the molecular currents, but the relation between B and H is really the same as in air. It is usual, however, among engineers to retain the symbol H for that small component of the magnetizing force which can be ascribed to the externally applied ampere-turns, and to ask no question about the molecular mechanism whereby it produces in iron a magnetic induction B so much greater than in air. In discussing the fundamental relations between electric and magnetic concepts it is very desirable to exclude such complex phenomena as the magnetization of iron and steel and, above all, such a fictitious complexity as a permanent magnetic point-pole of unit strength.

If one must have a magnet of unit pole strength, let it at least be an electromagnet—a coreless solenoid, the current in which can be adjusted to the correct value: a much more convenient procedure than stroking a knitting needle the requisite amount with a bar magnet, even in imagination. Moreover, one is not then likely to pretend that, having measured the force on the unit pole when placed at a given point in the magnetic field, one has determined something called H, whereas, if one had measured the force on a length of wire carrying a current one would have determined something called B. With a solenoid the assumption that the 'polarity' is concentrated at a point is the end of the make-believe, but with a permanent magnet it is but the beginning, for it is assumed that, if immersed in another medium of different permeability, the pole strength is unchanged; but seeing that 'pole strength' is a fiction which has only been defined in air, it is meaningless to say that it remains unchanged in another medium. When driven to be precise, most physicists would probably admit that they assume the total flux to remain constant, but such an admission undermines the basic nature of the unit pole.

In my opinion, we are concerned in reality with only two forces, namely, that between charges at rest and that between charges in motion, that is, between currents. Just as we write the gravitational formula

$$f = G\frac{M.M'}{L^2}$$

with a dimensional constant, so for the same reason we write (omitting trigonometrical coefficients and signs of integration)

$$f = \frac{1}{K}\cdot\frac{q}{r^2}\cdot q \quad \text{and} \quad f = \mu\,.\,\frac{ids}{r^2}\,.\,ids.$$

The classical formula $f = mm'/\mu r^2$ is merely the latter formula wrapped in mystery.

These two fundamental formulæ may be written

$$f = \frac{1}{K}\,.\,4\pi D\,.\,q = \mathcal{E}\,.\,q,\ \text{where}\ \frac{q}{r^2} = 4\pi D \quad \text{and}$$

$$\mathcal{E} = \frac{1}{K}\ 4\pi D,$$

and

$$f = \mu\,.\,H\,.\,ids = B\,.\,ids,$$

$$\text{where}\ \frac{ids}{r^2} = H\ \text{and}\ B = \mu H.$$

We are here confining our attention to space and not considering the numerical effects of a change of medium on K and μ. It is quite a mistake to imagine that the distinction between H and B is necessarily associated with ferromagnetism or with any assumptions as to its nature. The same applies to the distinction between D and $\mathcal{E}$, which is not necessarily associated with phenomena in material dielectrics.

The above formulæ are, of course, linked by the relation $i = dq/dt$, from which it follows that both $\mathcal{E}/B$ and H/D have the dimensions of velocity.

It will be seen from the above formulæ that $\mathcal{E}$ and B are measurable characteristics of the electric and magnetic fields, the former by the force on a stationary charge and the latter by the force on a current or moving charge, irrespective of the medium. D and H, however, are not directly measurable concepts. The displacement D is calculable at any point by dividing a charge by the square of a distance, that is, by an area; and similarly the magnetizing force H is calculable by dividing a current by a length. The latter is often expressed in ampere-turns per centimetre and is regarded as a localized cause producing at every point a magnetic induction B depending on the medium. *Similarly D appears as a calculated localized cause producing at every point a condition of space designated by $\mathcal{E}$ depending on the medium*; this is a reversal of the usual conception.

Some readers may object to the time-honoured magnetizing force H being relegated to the realms of unmeasurable concepts, and may quote from Prof. F. A. Lindemann's recent Guthrie Lecture (*Proc. Phys. Soc.*, 823; Nov. 1, 1936) that "a concept is meaningless unless it is in principle possible to observe the quantity which it typifies", but since both current and length will presumably be conceded as observable, their quotient can scarcely be dismissed as meaningless.

The procedure is analogous to that followed in the theory of elasticity and indeed throughout the whole of mechanical engineering. A load, that is, a force, is applied to a member, say, a tensile test specimen, and produces a strain or displacement at every point. One conceives this strain to be due to the stress at the point, this stress being an unmeasurable concept having the dimensions of a force divided by an area. Just as the mechanical engineer pictures the strain at a point as being due to a localized cause which he calls stress, so the electrical engineer pictures the magnetic condition at a point which he calls the magnetic induction B as being due to a localized cause which he calls the magnetizing force H. As the area integral of the stress is equal to the total applied force, so the line integral of the magnetizing force is equal to the total applied magneto-motive force or ampere-turns (neglecting numerical constants). If any reader feels disinclined to agree that mechanical stress is an unmeasurable concept I would refer him to p. 114 of Prof. R. V. Southwell's recently published "Theory of Elasticity", where he says:

> "External loads can be measured, and the displacements of points on the surface of a body (in the case of transparent materials we can make some attempt to measure the displacements of internal points); but *stress* (or internal action) has never been measured directly, and we can assert with some confidence that it never will. In these circumstances all that we can do is to construct a theory on assumptions which are consistent with experimental observations, and to look for confirmation of that theory to tests of particular conclusions—namely, predictions regarding displacements which can be measured."

It is to be noted that the one circuital equation

$$\frac{d\Phi}{dt} = A\,\frac{dB}{dt} = E = \mathcal{E}\,.\,l$$

involves only the directly measurable concepts, whilst the other

$$4\pi A\,\frac{dD}{dt} = m.m.f = H\,.\,l$$

involves only the non-measurable concepts.

On p. 299 of his book, Dr. Lanchester says, "In the opinion of the author it [μ_0 the permeability of space] is a mere number, a numeric". We can only say that we have failed to find anywhere in the book any valid reason, other than convenience, for this assumption, and that we have set out the above formulæ with the intention of showing clearly that there is no more reason for regarding μ_0 as a numeric than there is for making this assumption with regard to K_0. If, however, one assumes either explicitly or implicitly that a permanent magnet pole measures H, whilst a current-carrying conductor measures B, and then assumes that a permanent magnet is a conglomeration of molecular currents, it is little wonder that when one puts $B = \mu H$, one is able to prove that μ is merely a numeric.

In Appendix V, Sir James Henderson quotes Maxwell in support of the view that μ_0 is a dimensionless numeric, but the support is very unconvincing and one sentence is definitely against this view. The author attempts to brush this aside with the suggestion that Maxwell was nodding when he wrote the sentence, and he even goes so far as to rewrite it for him—to "re-mould it nearer to the Heart's Desire". We prefer to adopt a humbler role and to suggest that the quotation is by no means convincing that by "identical" Maxwell meant dimensionally and not merely numerically identical in the electromagnetic system of units, as the sentence which he dislikes certainly suggests. When Maxwell appears to support his view his "vision was wonderful"; when the support appears doubtful Maxwell's "clear view was obscured".

In Appendix VII Dr. Lanchester disagrees with Giorgi and the S.U N. Commission of the International Union of Pure and Applied Physics and concludes that "the M.K.S. or Giorgi system requires that the new unit of μ_0 shall be 10^7 c.g.s. units and not 10^{-7} as given in the various reports and memoranda". μ_0 is not a symbol for permeability but for one special permeability, namely, that of space, and we do not know what the author means by "the new unit of μ_0". He seems to have been confused by the unfortunate wording of the Report of the S.U.N. Commission, which stated that "the 'fourth unit' of the M.K.S. system is 10^{-7} henry per metre, the value assigned on that system to the permeability of space" This is very misleading. In the M.K.S. Giorgi system in which the absolute units of current, resistance, etc., are the ampere, ohm, etc., a medium to have unit permeability must be 10^7 times as permeable as space, and therefore the permeability of space, μ_0, is 10^{-7}, if expressed in M.K.S. Giorgi units. A further source of confusion is probably the introduction of the unit of inductance, the henry, into the definition, for although the dimensions of inductance are those of permeability multiplied by a length, its numerical value involves such things as the number of turns, and we have always regarded its inclusion in the Report as meaningless. It is not surprising that Dr. Lanchester has found it very confusing.

How much trouble has been caused by the persistent attempts to force by hook or by crook the electromagnetic concepts into the framework of L, M and T? Nothing in this book is more reasonable than the concluding paragraph of Rücker's paper, namely, that by not suppressing the secondary fundamental units such as μ and K,

> "I think that the symbols are thus made to express the limits of our knowledge and ignorance on the subject more exactly than if we arbitrarily assume that some one of the quantities involved is an abstract number."

The Giorgi suggestion to regard one of the electromagnetic concepts as fundamental is in keeping with this. If permeability be thus adopted as fundamental, there can be no question of its dimensions. The dimensions of length, mass, time and permeability are then L, M, T and 'μ', and just as certain values of the first three (C.G.S. or M.K.S.) are taken as units, so in the Giorgi system, unit permeability is 10^7 times that of space. All the electromagnetic concepts can be expressed dimensionally in terms of L, M, T and 'μ' without ambiguity and without making arbitrary and unjustifiable assumptions. If, in the future, Nature divulges some secret whereby the limits of our knowledge are extended so that we are able to express 'μ' in terms of L, M and T, the dimensional expressions can then be readily reduced to these three fundamentals; but in the meantime let us be honest with ourselves and not pretend to knowledge that we do not possess.

In Appendix VI Dr. Lanchester attempts to obtain light on the subject by calling in relativity, but seeing that it leads him to the conclusion that "a wave generated by a static charge undergoing acceleration will, in free space, be a wave having only magnetic characteristics, but which when arrested will revert to the static form", whereas "radiation from a magnetic pole or doublet would be wholly static in its manifestations until received and brought to rest", I am forced to conclude that in his search for light Dr. Lanchester has wandered into the outer darkness. In my opinion the author was unwise to include this section in a book the avowed object of which is to help the young engineer. G. W. O. HOWE.

(Berlin: Verlag Chemie, G.m.b.H., 1935–36.)

(1, 2 and 3) THE various hydrides and oxides of nitrogen comprise the subject matter of parts 2 and 3 of the volume on nitrogen, but aqueous solutions of ammonia and the oxyacids are not included. Prominence is given to the preparation of the raw materials used in the industrial synthesis of ammonia. It is pointed out that nitrogen extracted from air is very much cheaper than hydrogen, which comes chiefly from water-gas (51·8 per cent), coke-oven gas (30 per cent) and electrolytic plants (16·67 per cent). The Linde, Claude and Messer processes for extracting hydrogen from coke-oven gas are given very fully, as well as the synthesis of ammonia by the Haber-Bosch, Claude, Fauser and Mont Cenis methods. There is also an account of heavy ammonia, ND_3, which has been obtained pure by the action of deuterium oxide on magnesium nitride.

The action of different types of electric discharge upon air and other mixtures of oxygen and nitrogen is fully discussed, but the well-known processes of Birkeland-Eyde and Pauling are not described, since it is reported that they have been largely superseded and indeed contribute at present less than one half per cent of the world's production of synthetic fixed nitrogen. There is, however, a long list of publications upon the processes.

The fourth section of the volume on nitrogen contains an account of the oxyacids and their derivatives. It is stated that nitrous acid is still unknown in the free state, but its importance has attracted the attention of many investigators. Of the three possible structural formulæ, that one which has a semi-polar double bond is supported by evidence derived from the parachor. Among less familiar substances described are the somewhat evanescent compound nitroxyl, NOH, which polymerizes to hyponitrous acid, and pernitrous acid, O : N.O.OH, an isomer of nitric acid, arising from the interaction of hydrogen peroxide and sodium nitrite.

Compounds of the radical ammonium are so numerous and important that a whole volume has been devoted to its consideration. Sir Humphry Davy was the first to use the term ammonium and to point out its metallic properties, in particular its power of forming an amalgam, although the free radical is not yet known. That the ion has a tetrahedral structure was deduced by W. H. Mills from the optical activity of its quaternary salts. The present issue (Lief. 1) contains a full account of investigations of the system $NH_3 : H_2O$ and of the difficult problems connected with the basicity of ammonia. The extensive use of ammonium nitrate as an important constituent of high explosives was responsible for much work upon the properties of this polymorphic salt, a useful summary of which has been included.

(4 and 5). The production of special surface coatings to aluminium has become so important industrially that a whole part (*A* 3) is devoted to it, while numerous alloys of aluminium are described in another part (*A* 4). Both metals and non-metals are used for surfacing the metal, but whereas the former are chiefly used for decorative effects, the latter are mainly protective and greatly increase the usefulness of aluminium. Of particular interest is the electrochemical oxidation of the surface, the chief electrolytes used being chromic acid (in England), oxalic acid (in Germany and Japan) and sulphuric acid (in America). The last-named process is particularly adapted to the application of organic dyes to the oxide layer.

Alloys of aluminium have also attracted the attention of research workers in recent years to such an extent that some deviation from the general plan of the handbook has been adopted in order to collect together all those alloys which contain more than 50 per cent of aluminium. Special attention is given to alloys with silicon, which mixes with aluminium in all proportions in the liquid state, a simple eutectic system resulting on solidifying. The texture of the valuable eutectic alloy can be greatly improved by the addition of sodium or sodium fluoride.

(6) The technical uses of uranium are still very small in comparison with the amount of material rendered available as by-products in the extraction of radium. Uranium is used as a catalyst in the synthesis of ammonia, in the manufacture of steel, glass and ceramics and in dyeing and photography. A summary is given of the investigation of its isotopes, particularly of actino-uranium, with a probable atomic mass of 235, and of the synthetic radio elements beyond uranium.

Mohammedan Marriage Customs

Marriage Conditions in a Palestinian Village
By Dr. Hilma Granqvist. Vol. 1. Pp. vi +200. 75 Fmk. Vol. 2. (Societas Scientiarum Fennica : Commentationes Humanarum Litterarum, III, 8 and VI, 8.) Pp. 366. 160 Fmk. (Helsingfors : Akademische Buchhandlung ; Leipzig : Otto Harrassowitz, 1931, 1936.)

DR. HILMA GRANQVIST'S book is important both from a methodical point of view and on account of facts recorded in it. Her field studies were restricted to the village of Arṭās, situated south of Bethlehem at the edge of the Judaean desert and inhabited by Mohammedan Arabs. She examined all the information she was able to obtain regarding the marriages that had been contracted in the village during a period of a hundred years—in all, 264 marriages entered into by 199 men—and also procured information concerning a smaller number of marriages contracted by Arṭās women with men in other places. On the basis of her family lists she worked out statistics and compiled tables which formed a complement to the genealogical trees, and round this foundation the rest of her material was grouped.

This method has no doubt obvious advantages. The author writes: "In registering and discussing all the people in the village during four to five generations, we came upon a great many facts which would probably not otherwise have come to light, and the material appeared quite naturally, without having to be suggested in any way." On the other hand, it is a drawback that the genealogical method can be applied only to very limited areas, and it must also be admitted that it has not proved to be a key to so many doors as it has sometimes been supposed to unlock. Dr. Granqvist has widened the outlook by quoting numerous parallels or contrasts, remarks and references, found in printed sources relating both to Palestine and to other Mohammedan countries; but she has wisely relegated them to footnotes in order not to blur the picture given in the text.

Most of Dr. Granqvist's information was obtained from two native women recommended to her by Miss Louise Baldensperger, whose knowledge of Arṭās, where she had lived more than thirty years, was "of inestimable help and value" to the author. Those two informants learned to relate so slowly that their statements could be taken down word for word. The material is thus to a large extent a direct translation of the literal reports given by the women, but very frequently the translation is followed by the Arabic original. This is particularly the case with the copious songs, proverbs and formulæ found in the text, which, consequently, also should make the book a valuable contribution to Arabic dialectology.

The importance of Dr. Granqvist's investigations is enhanced by the fact that they have been made by a woman among women. In a society where the sexes are so secluded from each other as they are in the Mohammedan world, I think that the women can be properly studied only by members of their own sex; but in most cases the writers on Mohammedan marriage customs have been men. The author writes that those who have women as informants are in a specially favoured position, because "the women are very much interested in their conditions and linger with pleasure over things which the men glide over lightly". But as marriage is an institution in which both sexes are concerned, I also think that there are aspects of it which can be properly studied only by men.

A Mohammedan marriage is a complicated procedure, and Dr. Granqvist gives a graphic description of its successive stages. She has chapters on the age of marriage and child betrothal; the choice of a bride; the exchange of bride for bride and the bride price; the betrothal ceremonies and the making of the marriage contract; preparations for the wedding; the fetching of the bride; her arrival in the bridegroom's house; and the wedding week. There are chapters on the married woman in her husband's house and on her relation to her father's house, which are the more interesting since they deal with subjects that have not generally been sufficiently noticed in the literature on Mohammedan marriages. A woman is even after her marriage closely bound to her father's house, and her position in her husband's house is dependent on the esteem she enjoys and the support she can count upon in her old home. In critical situations she takes refuge there; when she is dissatisfied with the manner in which her husband treats her or when she is divorced by him. So also she is protected by her brother: "a man is even more responsible for his sister than for his wife and children".

The people themselves are said to find with surprise how well marriage generally turns out. Polygyny is certainly a disturbing factor; there is a saying that "the co-wife is bitter even if she were honey in a jar". But polygyny is not frequent in Arṭās, and in one great clan altogether lacking. A reason for this is the deficiency of women, which has compelled many men to take wives from other places. The author raises the question whether this deficiency may be due to the high percentage of cousin marriages, in accordance with my finding that in various cases inbreeding is combined with an excess of males. Thus, according to statistics of 1901, the small community of Samaritans at Nablus, who never marry outside of their own body, consists of 97 males and 55 females. Divorce is even less frequent in Arṭās than polygyny, which is contrary to the opinions generally held about Mohammedan peoples. While of the 199 married men 26 are or have been polygynous, only 10 have divorced their wives. The author admits that the infrequency of divorce is probably connected with the poverty of the village and the small number of women, but thinks available statistics would prove that the prevalence of divorce in the Mohammedan world has been greatly exaggerated. This is an altogether exceptional case in which Dr. Granqvist's study of the little Palestinian village has led her to such far-reaching speculations. A chapter on widower and widow concludes her remarkable book, which also contains excellent illustrations from photographs taken by the author.

EDWARD WESTERMARCK.

Die Fermente und ihre Wirkungen

Von Prof. Carl Oppenheimer. Supplement. Lief. 5. (Band 1: Specieller Teil: Haupt-Teil 12.) Pp. xii+641–781. (Den Haag: Dr. W. Junk, 1936.) 10 fl.

THE fifth delivery of this supplement continues the description of those enzymes which attack proteins, namely, the proteases and peptidases. It commences with two chapters of particular and general interest, one containing a discussion of some special questions relating to protein structure and the other being devoted to the question of the simplification of the true proteins by these enzymes. Both are of considerable value at the present time, when so much is uncertain in this intricate field of knowledge, and their study, though far from easy, will be helpful for those workers who are trying to bring some clarity into the subject.

The proteases are described in some detail under the headings of their qualitative and quantitative detection and their separation. About half the volume is devoted to the properties of the peptidases from a number of different aspects.

Magneto-optik (ohne Zeeman-Effekt)

(Handbuch der Experimentalphysik. Herausgegeben von W. Wien und F. Harms. Band 16, Teil 1.) Von Prof. Wilhelm Schütz. Pp. x+378. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1936.) 32 gold marks.

PROF. SCHÜTZ has ably carried out the task of co-ordinating and discussing the numerous experimental and theoretical researches on magneto-optics published up to the early part of the year 1936. More than half the book is naturally concerned with the Faraday effect. Since the appearance of Voigt's account of magneto-optics in 1916, much experimental and theoretical work has been done, not only on the normal diamagnetic rotation but also on the selective diamagnetic, the paramagnetic and the ferromagnetic rotations, and a convincing account of these topics is given. An interesting summary of various theories of the Faraday effect begins with the classical electron theory and goes up to the quantum-mechanical theories of Rosenfeld for atoms, and of Serber for molecules. The section under the heading of the transverse magnetic double refraction of light directs attention to the Voigt effect, but is particularly devoted to the Cotton-Mouton effect, for Prof. Cotton's powerful electromagnet has enabled him and his collaborators to obtain and measure effects beyond the ken of other observers. It is interesting to note (p. 218) how the measurement of the transverse magnetic double refraction in nitro-benzol can serve as a measure of the efficiency of an electromagnet.

A third section deals with the magnetic double refraction and dichroism of colloidal suspensions (Majorana effect), and of coarse suspensions of powdered crystals in liquids. In addition to Cotton's work, that of Procopiu at Jassy, Rumania, is prominent here. Experimental work on the magneto-optic Kerr effect is considered under the headings of polar, meridional and equatorial Kerr effects. The Voigt and Snow theories linking up the Kerr and Faraday effects to various optical constants of metals are amply discussed. Adequate mention is made throughout of the researches carried out in various countries, and Prof. Schütz's own important work is modestly treated.

The term 'gauss' is still preferred to 'oersted' as the name of the unit of magnetic intensity, and the plane of the electric vector is called the plane of polarization. Apart from a few trifling mis-spellings of proper names, the book appears remarkably free from defects. N. D.

Keris and other Malay Weapons

By G. B. Gardner. Second edition. Pp. 138. (Singapore: Progressive Publishing Co.; London: Bernard Quaritch, Ltd., 1936.) 6*s*. 6*d*.

THE author provides a complete survey of the *Keris*, enumerating its parts, main types and processes of manufacture. His general classification is clear and convincing, and marks a distinct advance in the study of oriental arms; it will be of special use to museum curators. It is noteworthy that his definitions are given in detail and used consistently. It is now, therefore, possible to classify this interesting local weapon and to discuss its typology with an agreed terminology.

As to its origins, Mr. Gardner quotes the use of the ray sting [*Ikan Pari*] as a *keris*, and directs attention to the thumb and finger grip it demands. He, also, follows Dr. van Stein Callenfels in his early dating (seventh century A.D.) for the all-metal, anthropomorphic *keris* Majapahit. Apart from this strange little weapon, the hilts of *keris* seem to fall into two main groups, based on a bird type and a demon type, both of which are found on the mainland, extending to the Shan area. Both these basic types, when over-foliated, would seem to merge in the well-known Madura 'flower'-hilt, which would, therefore, appear to be secondary. In any event, the *keris* Majapahit remains a little anomalous.

Mr. Gardner's notes upon *keris* magic are of special interest; sword magic has been somewhat neglected in the Orient, and is commoner than extant publications would suggest. K. de B. C.

The Official Year-Book of the Scientific and Learned Societies of Great Britain and Ireland;

with a Record of Publications issued during the Session 1935–1936. Compiled from Official Sources. Fifty-third Annual Issue. Pp. vii+170. (London: Charles Griffin and Co., Ltd., 1936.) 10*s*. net.

THE fifty-third annual issue of this year-book maintains the high standing that its predecessors have achieved, thus making it an indispensable guide in scientific, technical and other libraries, laboratories, universities, research institutions, etc. The learned societies are classified under fifteen headings, and this, together with a very full index, makes reference a very easy task. Under each society, association, etc., are given the list of officers, details of membership, arrangements for meetings, titles of publications, etc. The fact that all this information is gleaned from official sources makes the volume authoritative and one which is almost unique among the annual publications of reference literature.

Reactions of the Human Machine

By John Yerbury Dent. Pp. 288. (London: Victor Gollancz, Ltd., 1936.) 8*s*. 6*d*. net.

THE author of this lively and well-written book, besides being a medical practitioner, is quite clear that a doctor should also be something of a psychologist. The type of psychology which appeals to him is sufficiently indicated by the title. He has no use for "the older subjective language" which includes words like sensation, consciousness and will. Equally little use has he for the psycho-analytic libido and censor. He sees nothing in the "human machine" except the structure of the organism and its responses to environment. Few psychologists will agree with him; but his method of psychological approach has not prevented him from writing an extremely good book on its own lines, quite intelligible to the layman, and useful also to medical men.

Radium Beam Therapy and High-Voltage X-Rays*

By Prof. A. S. Eve, C.B.E., F.R.S., and L. G. Grimmett,
Radium Beam Therapy Research, London

THE quantity of radium now employed in the treatment of cancer, by the 'beam' method alone, exceeds 120 gm., with a value in excess of £800,000. The Continental names for this method are *telecurietherapie* and *Radiumfernbestrahlung*, while 'radium beam therapy' is the term commonly used in Great Britain. In this method of treatment a considerable quantity of radium (2–10 gm.) is surrounded by a large mass of lead or of tungsten alloy, and a beam of gamma-rays passes from the radium through a hole or window in the lead and is directed at the tumour or glands as may be desirable. A typical modern apparatus is shown in the photograph (Fig. 1).

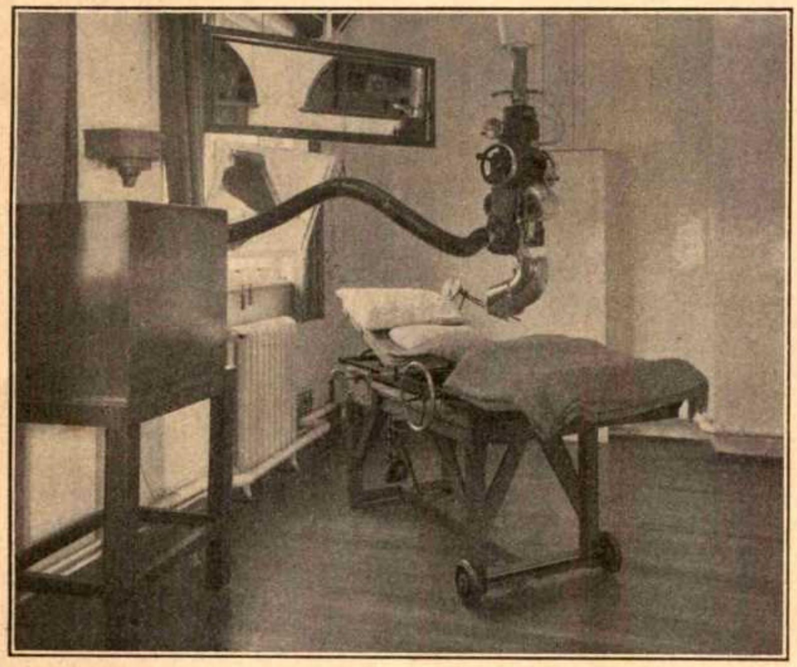

Fig. 1.
THE LATEST 5 GM. RADIUM UNIT OF THE RADIUM BEAM THERAPY RESEARCH, LONDON. THE RADIUM CAPSULE IS TRANSFERRED PNEUMATICALLY TO AND FROM THE LEAD STORAGE-SAFE TO THE UNIT, WHERE THE GAMMA RADIATION IS CANALIZED BY A MASS OF DENSE TUNGSTEN ALLOY. THE BEAM CAN BE ORIENTATED IN ANY DESIRED DIRECTION BY SCREW ADJUSTMENTS, AND THE DOSAGE CAN BE MEASURED AT ANY POINT.

In Table 1 is a list of institutions which are equipped for radium beam treatment.

One of the most complete radiation institutes is that recently built at Stockholm with funds collected to celebrate the jubilee of King Gustav V. It is a building of five stories, measuring about 170 ft. × 190 ft., well provided with radium and X-ray apparatus, together with all modern conveniences for examining, treating and nursing patients. There are arrangements for keeping records of all cancer cases in Sweden. The institute has an able staff of therapists, pathologists and physicists, and the whole organization is part of the new University Hospital at Stockholm. Any country desirous of establishing an efficient radiological institute would do well to study the Swedish scheme. A full description of the building is given in a booklet published by Norstedt and Söner, Stockholm.

A great weakness of radium beam therapy in the past has been the lack of a good system of dosage units. Now, however, thanks to the physical research of the last few years, it has become possible to express gamma-radiation in the international 'röntgen' or *r* unit, already so well established in X-ray therapy. The röntgen (*r*) is that quantity of radiation which, when secondary electrons are fully utilized, and wall effects avoided, produces ionization in air at 0° C. and 760 mm. mercury pressure, such that one electrostatic unit of charge per cubic centimetre is liberated at saturation current. The unification of X- and gamma-ray dosage units is a great step forward, and will hasten the solution of many of the controversial problems of radiology.

It is of the utmost importance that the beam of rays shall be suitably directed, that the dosage-rate at any particular part of the tumour or glands shall be known, and that the dosage shall be repeatable, or modified at will to any desired degree that experience may dictate. These purely physical problems have now been solved, and there is no longer any excuse for slipshod or haphazard treatment.

---

* This article has been published with the approval of the Executive Committee of the Radium Beam Therapy Research, on behalf of which we are glad to acknowledge the generous loan of 10 gm. of radium by the Union Minière du Haut Katanga.

In planning for the future, it is impossible to ignore the rival claims of radium and X-rays. Many radiologists believe that gamma-ray therapy is superior to X-ray therapy in its biological effects, and they attribute this superiority to the shorter wave-length of the gamma-rays; encouraged by this belief, they are striving after X-rays generated at higher and higher voltages, which approach the gamma-rays of radium in their nature. While there are many who would contest this point of view vigorously, yet since it is the motive which prompts the building of high-voltage X-ray plants, we may be permitted, without entering into a discussion of such controversial points, to inquire how far an X-ray tube working at, let us say, 1 million volts is capable of imitating the radiation emitted by radium.

The nature of the radium spectrum has been known for a long time. It consists of a small number of sharp monochromatic 'lines' with energies ranging from a few kilovolts up to 2·2 million volts. They are represented in Fig. 2 by a number of vertical lines the heights of which are proportional to the intensity of the radiations. These data have been taken from "Radiations from Radioactive Substances" by Rutherford, Chadwick and Ellis, in conjunction with the latest values of the photoelectric coefficients.

An X-ray tube working at 1 million volts yields a continuous spectrum with a sharply defined short-wave limit at 1 million volts. The bulk of the radiation output corresponds to a voltage considerably less than 1 million volts. No data have as yet been published on the spectral distribution obtained with high-voltage X-ray tubes, but we can obtain some idea of its nature by extrapolating Kramer's law, which holds very well for lower voltages of the order 100 kv. According to Kramer's law, the energy in the continuous spectrum which is included between the frequencies ν and $(\nu + d\nu)$ is given by:

$$I\,d\nu = \frac{8\pi}{3\sqrt{3}l} \times \frac{e^2h}{mc^3} \times Z\,(\nu_0 - \nu)\,d\nu\,;$$

where ν_0 is the frequency of the short-wave limit, l is a numerical factor of order 6, Z the atomic number of the target, and the remaining symbols have the usual significance. If we fix the material of the target, and change the variable from the frequency ν to the wave-length λ, we may write:

$$I_\lambda = \text{const.}\ V^2\,(V_0 - V)\,;$$

where V_0 is the maximum voltage applied, and V is the voltage corresponding to the wave-length λ. The relative values of I_λ calculated in this way for the unfiltered radiations are given in Table 2, together with the relative values of I_λ after filtration with 1 mm. and 2 mm. lead. The latest available absorption data of Read and of Jones have been used in calculating the transmission through the filters.

TABLE 2.

Probable Energy Distribution in Continuous Spectrum of a Million-volt X-ray Tube, based on Kramer's Law.

Wave-length	Equivalent Voltage	Relative Intensities I_λ		
		Unfiltered	1 mm. Pb	2 mm. Pb
	kilovolts			
12·35 X.U.	1000	0	0	0
13·0	950	452	407	387
13·8	900	810	725	645
14·5	850	1080	961	855
15·4	800	1280	1140	1000
16·5	750	1410	1240	1100
17·6	700	1470	1290	1120
19·0	650	1480	1280	1120
20·7	600	1440	1240	1060
22·5	550	1370	1160	990
24·6	500	1250	1040	870
30·8	400	960	745	580
41·1	300	630	405	260
49·3	250	470	243	128
61·5	200	320	111	29
82·2	150	19·1	2·1	2·3
123·5	100	9	0·2	—

The three curves corresponding to no filter, and filters of 1 mm. and 2 mm. lead respectively, are drawn, together with the radium spectrum, in Fig. 2. The great disparity between the radium spectrum and that of the million-volt X-ray tube is evident. The peak of the X-radiation output occurs at a value between 600 and 700 kilovolts. There is very little radiation at 1 million volts and nothing at all beyond this value. On the other hand, a considerable portion of the radium spectrum is located above 1 million volts, with a particularly intense line at 1·8 million volts. To generate radiation comparable in quality with the gamma-rays of radium a voltage approaching 3 million would be required! Assuming that the engineering difficulties were overcome, it is not certain that electrons driven by 3 million volts on to a target would expend all their energy in the production of röntgen rays, as other transmutations might take place.

The greater energy emitted by an X-ray tube is of some advantage. It is not difficult to make an X-ray tube the output in ergs of which is equivalent to that from some hundreds of grams of radium. This allows the tube to be used at a distance of 1–2 metres from the patient's skin, giving a practically parallel beam resulting in a high 'depth dose', that is, a high ratio between the tumour-dose at a depth, and the surface-dose on the skin. For it must be remembered that the skin reaction is the limiting factor in treatment. With the relatively small quantities of radium which are available for beam treatment, it is necessary to work with the radium sources so close to the skin as 5–10 cm. in order to obtain intensities capable of producing biological effects. This results in a strongly divergent beam, and a poor depth-dose. This point is well illustrated in Table 3, which gives the percentage depth-dose, as measured in water, at a distance of 10 cm. below the surface for various kinds of radiation at different distances from the surface.

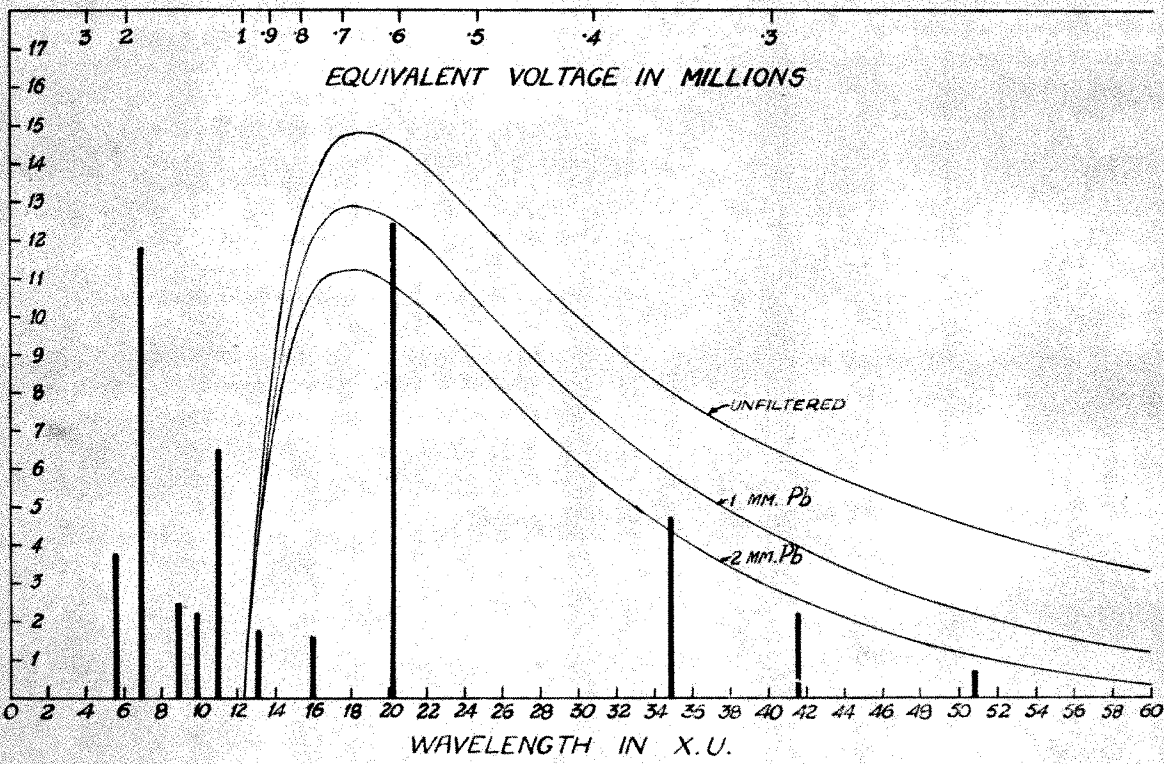

Fig. 2.

COMPARISON OF THE GAMMA-RAY LINE SPECTRUM OF RADIUM WITH THE CONTINUOUS SPECTRUM FROM A MILLION VOLT X-RAY TUBE, CALCULATED ACCORDING TO KRAMER'S LAW, FOR DIFFERENT FILTRATIONS.

TABLE 3.

Depth Doses Measured in Water.

Radiation source	Filter	Distance from surface	Percentage depth dose 10 cm. below surface
X-rays, 370 k.v.	5 mm. Cu.	75 cm.	43 per cent
X-rays, 200 k.v.	0·5 mm Cu.	75 cm.	36
Radium point source	0·5 mm. Pt.	5 cm.	11
[Radium point source	0·5 mm. Pt.	75 cm.	58]

We thus have the paradoxical situation that the more penetrating radiation appears to penetrate less. The fact is that both radium and X-ray treatments are governed by the inverse square law, and that the superior penetrating power of gamma-rays cannot be exploited unless prohibitive quantities of radium are available to make it possible to work with large radium-skin distances (cf. last line of Table 3). Even radiologists themselves are apt to lose sight of this important point and often stress, unduly and erroneously, the high penetration of gamma-rays.

The true advantage of radium treatment would therefore seem to depend on the property that *a great part of the electromagnetic waves proceeding* *from radium are shorter in wave-length than those that emerge from any X-ray tube at present in use.*

It is possible that in a few years time the new discoveries of physics, the neutron and artificial radioactivity, will find a place in radiation therapy. Already, in the United States, neutron beams are available of sufficiently high intensity to produce strong biological effects; their mode of action must differ in many respects from the radiations with which radiologists are familiar. Also it is now possible to obtain gamma-rays from artificial radioactive substances with energies far in excess of anything which radium emits. Radio-sodium, for example, disintegrates with emission of gamma-rays having energies in excess of 3 million volts. This substance has already been produced in weighable quantities; if it should prove possible to make it cheaply in bulk, it could be inserted daily into a radium unit of conventional design, and used for treatment in place of radium. All the knowledge which has been accumulated for radium beam therapy in the past could be brought to bear on the powerful new radiation.

In the meantime, it is of the greatest importance that there should be competent comparisons of the effects of radium and X-ray treatment, in which therapists, pathologists, biologists and physicists may make a thorough study of the results produced in living tissue, whether healthy or diseased, and explore to the full the new methods which the advance of physics is making available.

Biological Work of the Oxford University Expedition to North-East Land, 1935-36

By D. B. Keith

NORTH-EAST LAND is the second largest island of the Spitsbergen archipelago and lies astride the parallel of 80° N. Until a few years ago, it remained virtually an unknown land of evil repute. It was thought to lie outside the influence of the Gulf Stream and therefore to suffer from a far severer climate than the rest of Spitsbergen. The Oxford University Expedition, under the leadership of A. R. Glen, was the first expedition to winter in the country, and besides the radio research work, glaciology, survey and other activities of the expedition (see NATURE, Jan. 2, p. 10), biological work was carried out through the year.

It may be said at the start that the animal life of North-East Land is incredibly meagre, and the reason for the great difference between there and the rest of Spitsbergen is the very much colder summer conditions prevailing on the island. The winter, too, is severer, but this has not the same effect on the animal life; but when it is realized that the temperature in the summer months very rarely rises above 40° F., that snow storms are liable to occur at any time and that strong winds are almost continuous, it is not hard to see the reason for the paucity of animal life. It is probably not quite true to say that the Gulf Stream has no effect on North-East Land, for it now seems almost certain that the north-western coast does come under its influence, but its effect here is so small that the air temperature is invariably low and the weather usually windy and misty.

The difference between North-East Land and even the nearest areas of New Friesland is at once apparent in the vegetation. In North-East Land, the vegetation type most common is so open that it seems impossible to believe that biotic factors have played any part in its formation, whilst even in such areas as Treurenberg Bay and Lomme Bay, close plant communities are fairly extensive. In fact, the only areas in North-East Land where anything approaching close formations are to be found are in such places as the scree slopes below bird cliffs, areas (usually small islands) where colonies of eiders or terns are nesting, or, in a smaller way, round old nests of eiders, brent geese or glaucous gulls. Much of my biological work this summer was carried out in Murchison Bay, a large bay on the western coast, thickly dotted with islands, but one of which almost all the surrounding country is composed of dolomite. The sterility of the vegetation in such an area defies description. The rock weathers into fragments which are found covering great areas and lying loosely over the surface, entirely prohibiting any plant growth. Here and there a few specimens of *Saxifraga oppositifolia* or *Papaver radicatum* may have been able to take root; but it is almost true to say that the only places where plants are found are those where there has been manuring in some form or another.

My main work was a study of the birds, and here again the same may be said with regard to the paucity both of species and individuals. So far, only twenty-seven species of birds have been recorded from North-East Land, and of these only some sixteen breed regularly. As the base hut was built on a small area of level ground at the foot of a wall of towering basaltic cliffs, which in the summer were tenanted by nesting fulmars and Mandt's guillemots, I had a good opportunity for watching the arrival of these birds in the spring, which was of particular interest for the fact that the guillemots used at first to spend only certain hours each day at the cliffs.

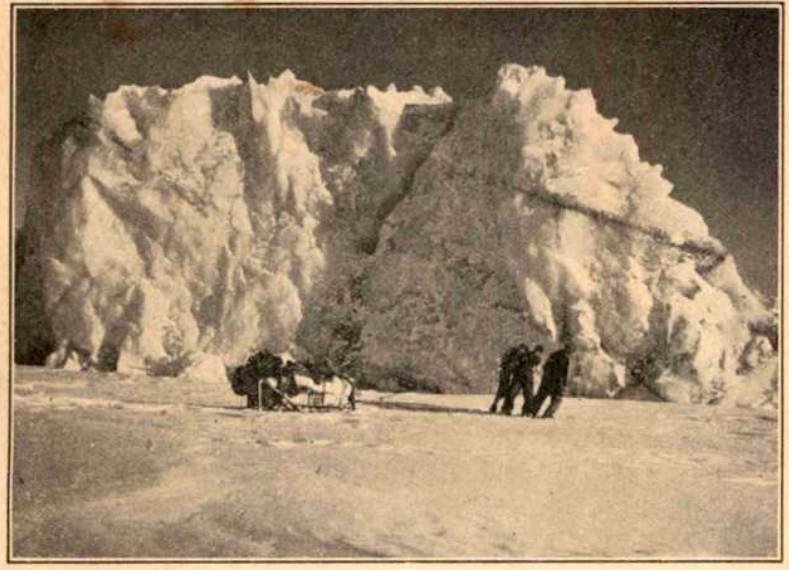

Fig. 1.
SLEDGING DOWN EQUIPMENT FOR THE BIOLOGICAL STATION IN MURCHISON BAY. PASSING AN ICEBERG WHILE TRAVELLING OVER THE FROZEN LADY FRANKLIN BAY.

The first sign of life in 1936, apart from a few solitary bears and one or two reindeer, was when a fulmar was seen flying silently along the face of the cliff in the half light of February 15, more than a week before the sun rose. Nothing else was seen until March 10, when four Mandt's guillemots visited the cliffs. This was the beginning of a long series of visits, for the guillemots arrived every night and left again early in the morning. As the month progressed they spent longer times at the cliffs, but these were always deserted in the afternoons. By March 19 the numbers had increased and the birds were staying until about 11 a.m. By March 31 they were arriving at 1 or 2 a.m., but leaving again at about 7 a.m. Gradually they began to arrive earlier and stay later. This curious habit of deserting the cliffs in the afternoon was not followed by the fulmars, which began to arrive after April 7. In the night and morning the cliffs were shared by guillemots and fulmars, but in the afternoons the latter were in solitary possession; and this continued until the end of April, when guillemots began to stay at the cliffs throughout the day.

The first nest I found was one of a red-throated diver, which on June 21 contained one egg (Fig. 3). From that date the divers and eiders began to nest, but it at once became evident that though the former were nesting in normal numbers, that is, there was a breeding pair on almost every freshwater tarn of suitable size, only a very small percentage of the ducks were breeding at all. This non-breeding, which this year was found in the case of the eider and brent geese, is a regular feature of arctic bird life and one of great interest. From work done all over the Arctic, notably in Greenland and Spitsbergen, it seems fairly certain that every fourth year or so certain species of birds are affected, and of these

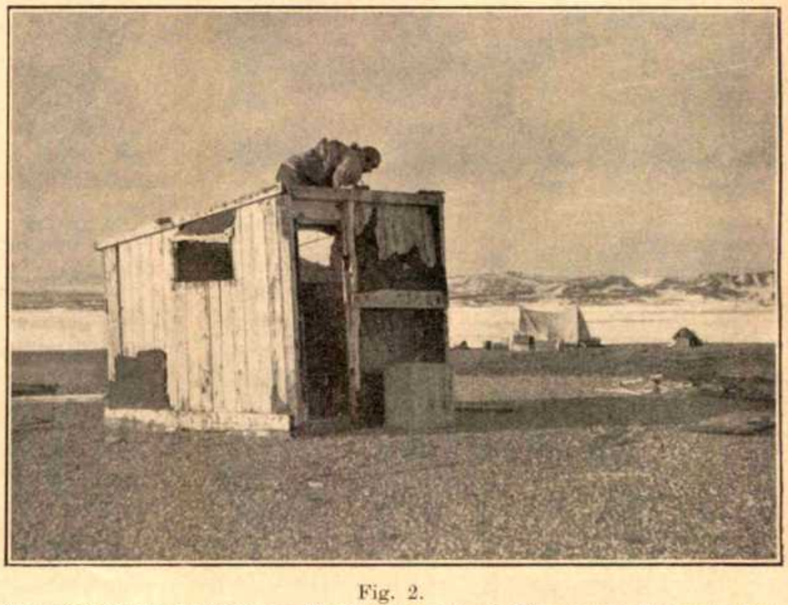

Fig. 2.
THE BIOLOGICAL STATION ON RUSSIAN ISLAND IN MURCHISON BAY OCCUPIED BY KEITH AND GODFREY FROM APRIL UNTIL JULY, 1936.

species many less than the normal percentages are found breeding. The birds most commonly found to be affected are the ducks, geese and divers, but in North-East Land the divers were breeding in normal numbers.

It is as yet difficult to account for this phenomenon. Many and varied suggestions have from time to time been put forward. It would appear that it must bear some relation to changing climatic conditions, as these must be assumed to be the only variable factor in the environment of the birds until some variation at present unknown is shown to take place in their marine food supply. But this leaves us with the difficulty of explaining the regularity of the occurrence of the non-breeding years by climatic changes which have not yet been shown to follow the necessary cycle of 3–4 years. The late melting of the sea-ice and disappearance of the snow from the land might in some cases give an explanation, but this cannot find universal acceptance because in a non-breeding year the birds that do breed do not usually begin to nest any later than usual. Again, such a condition could scarcely affect the ducks without to some extent also affecting the red-throated divers. It is also impossible to suppose some general factor which affects reproduction throughout the Arctic, because species such as the waders and passerines have never yet been shown to be affected in this way. During the earlier part of the summer, I examined the gonads of many eiders, and the general result was that the ovaries were scarcely enlarged at all, but that the testes of the drakes were developed to the normal size of a breeding bird. It would be unwise as yet to argue from this one case, but if similar observations are carried out elsewhere and the same result found, the reason for the non-breeding will have to be found in some factor which affects the sexual development of the female and not of the male. It was noticeable throughout the first part of the summer how much more sexually excited the drakes were than the ducks.

Even in normal years North-East Land has a large non-breeding population, but this is entirely different from that which I have been describing above. The island lies at the extremity of the breeding area of most birds visiting it, and it seems to a large extent to be populated by birds which were bred elsewhere and have had to move out from the more favoured areas of their range to this uninviting marginal territory. Only by this supposition can I account for the large non-breeding population which seems to be a normal feature in every species. It is difficult to estimate non-breeding percentages among cliff nesting species, but it was abundantly clear that large numbers of non-breeding Arctic skuas, terns, grey phalarope, purple sandpipers and snow buntings were a normal feature of the ornithology of North-East Land. It was also clear that the numbers of each species which were breeding were quite inadequate to maintain the status of that species with anything like a normal rate of mortality.

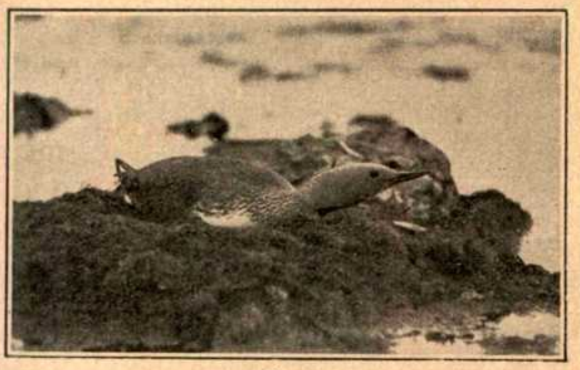

Fig. 3.
RED-THROATED DIVER ON NEST.

This question of non-breeding both in normal and abnormal years is one of the most interesting confronting the ornithologist visiting North-East Land, and I have but touched on it here. Another problem is that of distribution. North-East Land is an excellent field for this and other inquiries, as the factors which have to be considered can be so much more easily seen there than in more temperate regions with their more complex bird communities.

Obituary Notices

Sir Grafton Elliot Smith, F.R.S.

WITH deep regret we record the death of Sir Grafton Elliot Smith, the famous anthropologist and former professor of anatomy in the University of London (University College), which took place at Broadstairs on January 1 after a prolonged period of ill-health, at the age of sixty-five years.

Grafton Elliot Smith was born on August 15, 1871, at Grafton, New South Wales, and was educated at the Universities of Sydney, where he obtained the degree of doctor of medicine in 1895, and Cambridge, where he was a fellow of St. John's College, on which foundation he afterwards became an honorary fellow. On obtaining his degree in medicine, he devoted himself especially to the study of the comparative anatomy of the brain. Not only did this orientation of his studies largely determine his future achievement by directing his attention to human palæontology and the problems of the evolution of man, but also the publication of the results of his early researches in the *Journal of Anatomy* and other professional periodicals speedily won him wide recognition as one of the foremost authorities on the anatomy of the brain.

Of little less importance, however, in influencing the development of Elliot Smith's thought and the direction of his studies was his appointment to the chair of anatomy in the Egyptian Royal School of Medicine, Cairo. Here he was brought into contact with a number of problems arising out of investigation of the history and culture of the ancient Egyptians, which were germane to his own studies. Skeletal remains from predynastic and dynastic burials in almost countless numbers, and mummies from the various periods of Egyptian history, were studied on his own initiative or were brought to him for examination and report. In particular, he was deeply impressed by the character of the skeletal remains obtained by G. A. Reisner from his Nubian excavations. With this material under his hand, Elliot Smith was attracted inevitably to the consideration of such questions as the racial origins and composition of the ancient Egyptian population, their pathology and the incidence of diseases among them, as well as the history and development of the practice and technique of mummification as manifested in the anatomical evidence. Nor did his active mind rest there; he was drawn on to examine the cultural and religious ideas with their modifications in course of time, which were implicated in all this material. In communications, for example, submitted to Section H (Anthropology) of the British Association so long ago as the Dublin meeting of 1908 may be discerned the germ of ideas and concepts which were to play a very important part in the work of his later years.

In 1907 Elliot Smith was admitted a fellow of the Royal Society. His services to scientific studies in Egypt were recognized by the award of the Order of the Mejidie. In 1909 he left Egypt to occupy the chair of anatomy in the University of Manchester. Apart from a number of papers contributed to scientific journals, the most important of his publications arising directly out of his work in Egypt was "The Royal Mummies", which as a result of the anatomical examination of well-known examples from the Royal burials, threw a new light on certain dynastic problems of Egyptian history. It was published in 1912.

Of more immediate consequence in Elliot Smith's career was the publication in 1911 of his "Ancient Egyptians", which was received with enthusiasm by many anthropologists, notably the late W. H. R. Rivers. Here, working largely on evidence afforded by the skeletal material obtained by Reisner, to which he had had access though it long remained unpublished, as well as on material from burials at Gizeh, he deduced the intrusion of a new racial element of Asiatic (Armenoid) origin into the population of early dynastic Egypt. To these people he attributed the introduction of metal tools, facilitating the working of stone, and consequently, as he had been led to believe by his study of the *mastaba* and other forms of Egyptian burial practice, leading up to the erection in stone as a sepulchral monument, of which the idea had been carried far and wide in the early world to give rise to the widely distributed megalithic monument. The publication of this book is a landmark in Elliot Smith's development as an anthropologist.

In the following year (1912) Elliot Smith presided over Section H (Anthropology) of the British Association at the Dundee meeting. Through his personal influence with former pupils and friends, as well as by his own contributions, the proceedings of the Section on this occasion gave the members of the Association a remarkable review of certain aspects of Egyptological studies at the time.

Elliot Smith's most noteworthy part in the proceedings at Dundee, however, and at the same time his most considerable contribution to anthropological science on this occasion, as perhaps might be expected, lay in his presidential address. In this he dealt with the identification of the neopallium, the associational area in the frontal region of the brain, and demonstrated its bearing upon the evolutionary problem in man, views then made known to a wider public for the first time. Notwithstanding the fact that subsequent neurological research has led to the very considerable modification of Elliot Smith's views on this localization of function, the conclusions which were there put forward on the development of man's faculties in the evolution from lower forms of life afforded a great stimulus to further research on such questions as the development of stereoscopic vision, of speech and generally on the evolution of form and function. This address, in fact, marks a stage in the study of the brain of early man, of which the development, more especially by the use of the endocranial cast, was probably Elliot Smith's greatest and most lasting contribution to the study of human palæontology.

The announcement, which followed shortly after, of the discovery of the Piltdown skull, brought Elliot Smith into the discussions which followed on the reconstruction of that early relic of man, and it was under his supervision and with his collaboration that the late Dr. J. Hunter, after the Great War, effected a reconstruction of the cranium, which once and for all brought the chimpanzoid jaw into sufficiently harmonious relation with the rest of the skull to place the individual and human character of both elements, which had been questioned, beyond doubt.

Elliot Smith by now was recognized as one of the foremost authorities on early man, and with Sir Arthur Keith divided the honours of arbiter in pronouncing upon the character and importance of any new discovery. He was the first to demonstrate the Rhodesian skull before the Zoological Society and the Royal Anthropological Institute in 1921, and he described the "Lady of Lloyds'", the primitive skull found in the City of London in 1925, which, as he showed at the International Congress of Prehistoric and Protohistoric Sciences in London in 1932, may possibly be the earliest known example of the 'modern' type of man. An account of this skull appears in the second edition of his "Evolution of Man", first published in 1924. It is perhaps worth while to recall that Prof. Raymond Dart, whose sensational discovery of *Australopithecus* in South Africa in 1925 caused no little controversy, was one of the many pupils whom Elliot Smith inspired with his own enthusiasms.

It was, however, in connexion with the discovery of Peking man that Elliot Smith was perhaps most active. He spared himself no pains to become fully acquainted with this early type of man in all its bearings, and to make it known to his colleagues and a wider public. He was able to speak with especial authority, as not only was he kept fully informed of the progress of investigation through his friendship with the late Davidson Black, but in his visits to the Far East he personally examined the relics of Peking man and informed himself on the geological and topographical conditions of discovery. Only a few weeks ago, in December last, a letter to *The Times* confirmed the importance of the latest discoveries and gave full credit to the work of Prof. Franz Weidenreich, the new director of the Cænozoic Laboratory, an appointment which Elliot Smith himself had recommended to the Rockefeller Trustees, although the nominee had been an acute critic of his own work.

In the meantime, while Elliot Smith had attained a commanding position as an authority on the evolution of early man, his activities in other directions had involved him in violent and sometimes embittered controversy. The ideas which were adumbrated in his view of the spread of the megalith put forward in his "Ancient Egyptians" in 1911 had undergone a wide development. In his study of mummification he had been much impressed by the similarities, or identities as he saw them, in the technical methods employed by the ancient Egyptians and in those which had been practised on the mummies brought back by the Cambridge Expedition to the Torres Straits in 1900. Further study of the ethnographical record of primitive peoples and of the peoples of antiquity convinced him that similarities in the cultures of the world at large were to be explained as the result of a wide diffusion of culture which had Egypt as its starting point. The earliest full statement of this theory, from which sprang the 'Historical School', appeared in a paper in the proceedings of the Manchester Literary and Philosophical Society, afterwards published (1915) as "The Migrations of Early Culture". It was developed further in "The Evolution of the Dragon" (1919), "Elephants and Ethnologists" (1924) and other works; it finds its best and most philosophical expression perhaps in "Human History" (1930). The development of this school of thought, which was opposed by its originator to the Tylorian system, or 'Evolutionary School', as Elliot Smith termed it, owed much to the work of W. J. Perry, an assistance of which Elliot Smith was ever generous in acknowledgement.

This is neither the occasion nor the place to enter into any critical examination of Elliot Smith's views on the subject, nor to dwell upon the opposition which they aroused. In fairness to him, two things must be said, one personal and one in relation to the development of his work at University College, where he succeeded the late G. D. Thane as professor of anatomy in the University of London in 1919. Elliot Smith was a man capable of inspiring in those who were well acquainted with him an admiration and affection which never faltered; but he had a nature which was extremely sensitive and reacted to criticism in the release of a pen which knew no mercy. Hence he frequently involved himself in unnecessary and acrimonious debate which might and should have been avoided with better understanding.

On the broader issue, it has perhaps too seldom been noted to how great an extent Elliot Smith's theories on the diffusion of culture were a counterpart of, and were influenced by, his views on the origin and distribution of races. Not indeed that he would have pressed too hard his conception of racial filiation and affinities. No one who heard his impressive denunciation of the misuse and misinterpretation of racial theory in the interests of political prejudice, when he presided over the Section of Physical Anthropology at the International Congress of Ethnological Sciences in London in 1934, could have remained under any misapprehension on this point. But there can be no doubt that he looked upon culture very much as an original stock spreading over the world from one centre of origin, which he found in Egypt, as a concomitant and an analogue of the spread of the stock of *Homo sapiens* to develop into the variety of the races of man in a diversity of local conditions. Such a filiation of racial characters, for example, was his hypothetical "Brown Race" extending from the Mediterranean to India and beyond, which has afforded physical anthropologist and archæologist alike a valuable theoretical basis for racial argument, in unravelling the ethnic and cultural history of the Mediterranean and Near and Middle East.

It was this concept of the fundamental unity and parallelism in the study of man, which was clearly before Elliot Smith's mind when he proceeded to remodel his Department at University College with the assistance of the grants which had been received from the Rockefeller Trustees. There he planned that the study of man's evolution and physical structure in the Department of Anatomy should proceed side by side with the study of the development of culture on the lines which he had worked out. This scheme he was able to bring to fruition with the appointment of Dr. W. J. Perry as reader in cultural anthropology in 1927.

When Elliot Smith retired owing to failing health at the close of the academic year 1935–36, he had been the recipient of many honours in recognition of his services to science. In 1934 he was knighted. He had been a member of the General Medical Council, and was formerly a vice-president of the Royal Society, from which he received a Royal Medal;

he received the Hon. Gold Medal of the Royal College of Surgeons of England, and the Prix Fauvelle of the Anthropological Society of Paris. He had delivered the Croonian Lecture, the Arris and Gale Lecture, the Huxley Lecture of Birmingham, the Imperial College and the Royal Anthropological Institute, as well as lectures of like standing in the medical colleges of Edinburgh, Dublin and the University of New York. He had been president of the Anatomical Society and the Manchester Literary and Philosophical Society among other societies concerned with his special studies, and his work had been recognized on the Continent by honorary fellowship or corresponding membership of the academies and more important anthropological societies of France, Holland, Belgium, Germany and Italy.

Dr. C. V. Jackson

Dr. C. V. Jackson, who at the early age of thirty years lost his life in a sleigh accident at St. Moritz on December 30, was a spectroscopist of considerable ability who had made valuable contributions to the establishment of accurate standards of wave-length. A graduate of the University of Oxford, he joined the Imperial College of Science and Technology about six years ago for the purpose of carrying on research in this subject under the direction of Prof. A. Fowler. On Prof. Fowler's retirement in 1934, he remained at the Imperial College as an honorary lecturer. His work included very precise interferometric measurements of iron, silicon, krypton and other spectrum lines, which were published in the *Proceedings of the Royal Society*, and he gave a considerable amount of attention also to the investigation of possible sources of light for the production of more satisfactory primary and secondary standards than those now accepted.

Dr. Jackson was a man of considerable financial resources, which he expended freely in the purchase of apparatus of the highest quality. His scientific work was characterized by quickness of mental apprehension and by an extreme fastidiousness in measurement which was in surprising contrast to the somewhat bewildering vagaries of his general temperament. He would alternate periods of intensive physical research with horse-racing and other social activities which are not usually found in such close association therewith. He was a member of the Commission on Wave-Length Standards of the International Astronomical Union, and attended the meetings of that body in Paris in 1935.

Dr. J. M. H. Munro

Before 1884, basic slag was a 'waste product', of which extensive spoil heaps had accumulated. It was the refuse of Bessemer steel converters which had been lined with basic mineral matter to abstract phosphates from the molten iron, and it contained about twenty per cent of phosphorus pentoxide (P_2O_5) combined mainly with lime. About forty years before that time, Lawes and Gilbert had demonstrated that the value of 'rock phosphate' as a fertilizer was greatly increased by treatment with sulphuric acid. The discovery by Wrightson and Munro of the fertilizing value of ground basic slag was of almost equal value to agriculture, and added vastly to the productivity of large areas of what were previously very poor pastures.

John May Herbert Munro, who died at Bath on November 6, at eighty-one years of age, matriculated at the age of seventeen and was one of the youngest men, if not the youngest, to graduate D.Sc. London five years later in 1877. His record included distinction in logic, botany and chemistry. In the early 'eighties, after having for a few years held an appointment in the Patent Office, he joined John Wrightson and William Fream in founding what was then the second of the English agricultural colleges, at Downton in Wiltshire. John Wrightson was a brother of Thomas Wrightson, whose firm of steel manufacturers was one of those which had used the basic process and accumulated spoil heaps of slag. The high phosphate content of the slag was, of course, known, but it did not occur to anyone that it could be used as a fertilizer until Wrightson and Munro demonstrated the fact by a series of agricultural and laboratory experiments at Downton in 1883 and 1884.

I came to know Munro and to visit him at Downton about that time when he was working out methods of determining the solubility of the P_2O_5 of the slag, its availability as a plant nutrient and the degree of 'fineness of grind', on which both depended. His extreme modesty prevented him, so far as I know, from ever claiming credit for this demonstration of the value of finely ground basic slag, which later became well known from experiments by Gilchrist and Somerville at Cockle Park, in Northumberland. At the same time, Munro was working in collaboration with Warington on problems connected with nitrogen fixation by the nodules of leguminous plants, a subject then in its infancy, and on which he published papers in the *Journal of the Chemical Society*. In 1892, I was fortunate in obtaining his collaboration in a long series of experiments at Warminster on the factors of productivity and of malting quality in barley, and in the forty years following, during which they have been in progress, I have had the inestimable benefit of his advice on the chemical problems involved. Later on, he deserted professional agriculture (except as an analyst) for medicine and bacteriology, and did valuable work on the composition and therapeutics of Bath mineral water.

E. S. Beaven.

We regret to announce the following deaths:

Prof. Louis M. Dennis, emeritus professor of chemistry in Cornell University, an authority on gas analysis, on December 9, aged seventy-three years.

Prof. D. F. Fraser-Harris, formerly professor of physiology in Dalhousie University, Nova Scotia, on January 3, aged sixty-nine years.

Geneviève Lady Watson, local secretary in Palestine to the Palestine Exploration Fund, on December 31, aged eighty-two years.

News and Views

Prof. V. L. Komarov

THE presidential chair in the U.S.S.R. Academy of Sciences, which became vacant last year owing to the death of Prof. A. P. Karpinsky, is now filled by the election of Prof. V. L. Komarov. The new president is an eminent botanist, particularly well known for his exhaustive studies in the flora and vegetation of Kamtchatka, Manchuria and the Far East generally. During the last few years, Prof. V. L. Komarov occupied the post of vice-president of the Academy and took an active part in various aspects of its work. It may be hoped that his election to the presidency will mean substantial developments in the natural history researches, which lately has remained somewhat in the background, since the main attention of the Academy, as a whole, has been directed to technical and engineering problems, which have to be studied in connexion with the 'socialistic reconstruction' of the country.

Alfred Willett (1837-1913)

THIS eminent London surgeon was born on January 3, 1837, the second son of William Catt of Brighton, who afterwards took the name of Willett. His medical education was carried out at the Sussex County Hospital, where he was a pupil for three years, and at St. Bartholomew's Hospital, London. After qualifying in 1859 he held a number of junior appointments at St. Bartholomew's Hospital, where he was successively elected assistant surgeon, surgeon in charge of the orthopædic department, full surgeon and lecturer in surgery. In 1897 he delivered the Bradshaw Lecture on "The Correction of Certain Deformities by Operative Measures upon Bones" at the Royal College of Surgeons, where he served on the Council from 1887 until 1903 and as vice-president in 1894 and 1897, but declined nomination for the presidency. Among the other appointments of distinction which he held were those of president to the Royal Medico-Chirurgical Society and of surgeon to Queen Charlotte's Lying-In Hospital and the Evelina Hospital for Children. Willett was an excellent example of the transitional period between the pre-Listerian era and that of antiseptic surgery. Undeterred by the unsympathetic attitude of his colleagues, he studied Lister's methods, and in the early eighties was the only surgeon in the hospital to perform systematic abdominal operations in conjunction with the celebrated gynæcologist, Dr. Matthews Duncan. The interest which he took in orthopædic surgery was rewarded by his successful treatment of deformities. His death took place twelve years after his retirement from St. Bartholomew's Hospital, on June 20, 1913. A silver medal named after him is awarded annually to the winner of the highest marks in operative surgery at the Brackenbury Surgical Examination at St. Bartholomew's Hospital.

Solar Eruptions and Radio Fade-outs

THE associated phenomena of a bright hydrogen eruption on the sun on December 3 and a radio fade-out, described in NATURE of December 12, p. 1017, had an interesting sequel 27 days later. On December 30, the sun was under continuous observation with the spectrohelioscope at the Royal Observatory, Greenwich, from $9^h\ 45^m$ to $12^h\ 55^m$ U.T., and at first attention was concentrated on a region near the central meridian which showed signs at $9^h\ 45^m$ of having been recently active. At $10^h\ 30^m$, a bright eruption began rapidly to develop there and lasted until about 11^h. At $10^h\ 57^m$, on turning to another part of the disk, a very bright and extensive hydrogen eruption was seen to have begun at a position about 55° west of the central meridian in latitude 22° north; in about 20 minutes this bright eruption had spread southwards to about latitude 14° north, so that the eruption when fully developed was spread over a distance of about 60,000 miles in latitude. (This active region was nearly identical in position with the region that was active on December 3.) It is shown by a whole disk spectroheliogram, taken in hydrogen light ($H\alpha$) by Mr. Evershed at his observatory at Ewhurst, that at $10^h\ 34^m$ this second and larger eruption on December 30 had not begun, though another spectroheliogram taken at $11^h\ 20^m$ (after information had been received from Greenwich) shows the eruption near its full development. The most probable time of the beginning of the eruption, derived by extrapolating an intensity curve given by photometric measures made at Greenwich after $10^h\ 57^m$, is about $10^h\ 50^m$. The declining stages of the eruption were relatively slow, and by $12^h\ 50^m$ the streaks of emission were of the normal brightness of ordinary flocculi.

IT is of considerable interest that three radio fade-outs were reported later as having occurred during the morning of December 30 on short-wave (of the order of 20 metres) wireless transmission between certain stations in the earth's sunlit hemisphere. The first of these occurred about an hour before the sun could be observed at Greenwich with the spectrohelioscope, but the disturbed appearance at $9^h\ 45^m$ of an area near the sun's central meridian may be significant; further solar data from observatories east of Greenwich may possibly be forthcoming. The second radio fade-out occurred from $10^h\ 31^m$ to $10^h\ 45^m$, and the third from $11^h\ 0^m$ to $11^h\ 20^m$. The agreement in time between the last two radio-fadings and the two bright hydrogen eruptions on the sun appears to be highly significant in view of the other occurrences to which attention has already been directed in NATURE. It must be mentioned, however, that radio experiments conducted in England on December 30, while the solar eruptions were in progress, indicate that the disturbed conditions of the ionospheric layers evident on December 3 were not reproduced on December 30.

"The Kiss Precise"

IN NATURE of June 20 last, we published some verses by Prof. F. Soddy under this title. Shortly afterwards, Mr. E. B. Wedmore sent two verses generalizing Prof. Soddy's equations for the circle and the sphere to space of n-dimensions, and more recently Mr. C. C. Mason has submitted a verse on similar lines. Prof. Soddy informs us that he received a verse (dated July 17, 1936) from Mr. Thorold Gosset, of 136 Chesterton Road, Cambridge, generalizing his equations, and, in response to his request, Mr. Gosset furnished a formal proof of the proposition later in the same month. Mr. Gosset seems to have extended the geometry of all the semi-regular figures to n-dimensions in a lengthy paper some forty years ago, but it remained unpublished, except for a few results which appeared without proofs in the *Messenger of Mathematics*. The existence of these figures has recently been rediscovered, some in Holland, some in England, and a paper by Dr. Coxeter on the subject has been published by the Royal Society, so that all are now known. Prof. Soddy's development of "The Kiss Precise" and "The Hexlet" appears elsewhere in this issue (p. 77). Dr. F. Morley has also recently furnished a formal proof of the hexlet, which is printed on p. 72. Mr. Gosset's fourth verse to the "Kiss Precise" is appended:

And let us not confine our cares
To simple circles, planes and spheres,
But rise to hyper flats and bends
Where kissing multiple appears.
In n-ic space the kissing pairs
Are hyperspheres, and Truth declares—
As $n + 2$ such osculate
Each with an $n + 1$ fold mate
The square of the sum of all the bends
Is n *times the sum of their squares.*

Museums and their Type Specimens

THE *Annals of the Transvaal Museum* (**18, 349–413**; **1936**) contain four papers by Dr. R. Broom. The list of the Karroo reptiles is increased by 15 new genera and 23 new species. Many of these are to be described in further detail elsewhere, and this information leads us to wonder with what object Dr. Broom now publishes abbreviated descriptions, the day for seeking priority in the accounts of new species being assuredly passed. The species are described almost exclusively on their skulls, and most of these, to judge by the figures, were capable of restoration. This process is obviously a fine art as seen in the occiput of *Notœlurops*, pictured as preserved and as restored. Clearly, in dealing with such a large and widely distributed fauna as that of the Karroo, it is best for the collector to reserve his more imperfect specimens rather than to describe such as "types". In this matter of "types" Broom has much to say in his "Review of some Recent Work on South African Fossil Reptiles" where he considers the publications of ten workers. The most prolific of these was Boonstra, who has contributed no less than twenty-four papers in the last six years.

OBVIOUSLY this output can only have been possible on a very different technique from the laborious chipping away of the matrix in which the skull is embedded, this being usually regarded as the safest method in developing a skull. Boonstra worked in the British Museum, and we learn how he dealt with a type specimen of *Theriognathus* Owen (1876), fracturing it in several places with a hammer and chisel. "The specimen now is of more value to the morphologist", but surely such an operation should only have been performed by the skilled preparators of the Museum. In another specimen Boonstra failed to find two small canines which had been figured and so ground down the type to see their roots. Broom regards these operations on type specimens carried out by a visitor as "a gross breach of trust" on the part of a Museum to which "types" are supposed to be sacrosanct. This is a serious statement, damaging in that it is likely to deflect the flow of material to the Museum. Obviously it calls for a statement on behalf of the Museum as to whether the operations are correctly described and were specifically authorized by its responsible officers.

Radio Research in India

MANY readers of NATURE will recall that, during his recent visit to Great Britain, Prof. S. K. Mitra expressed a desire to see a Radio Research Board established in India to carry out research of a fundamental nature on radio communication in a manner analogous to the working of the corresponding British Board. While this scheme had the enthusiastic support of eminent British authorities, there appears to be some difficulty in getting the Government of India to take a favourable view of the project. An article in the *Amrita Bazar Patrika* refers to a speech made recently on this subject in the Physics Department of the University of Allahabad. It is reported that in the opinion of the Government, the research station attached to the All-India Radio Organization will be able to conduct all the research work required for the time being. As Prof. Mitra points out, however, there is a great need for the setting up of a fully equipped Radio Research Board laboratory where more fundamental work can be conducted by experienced workers from the universities without in any way overlapping or interfering with the more applied work of the broadcasting organization. In England, the British Broadcasting Corporation conducts research on its own particular problems independently of the wider and more fundamental work of the Radio Research Board. Arrangements are in force whereby close liaison is maintained between the two organizations as necessary, and this is found to be of mutual advantage.

THE article referred to above also records a speech by Prof. M. Saha of the University of Allahabad, who is closely associated with Prof. Mitra in his efforts to obtain more support for research on radio problems. Prof. Saha complains, however, that the apathetic attitude of the authorities towards scientific research is not confined to radio matters. Many research chemists and physicists in India have to carry out their research while working in ill-equipped laboratories under various difficulties arising from insufficient financial provision. In these circumstances, it is certainly very creditable that some of these workers have been able to achieve international renown, but it is highly probable that a little more encouragement on the financial side would be amply repaid in the increase in knowledge and its resulting benefits both to India and the world at large.

Problems of Industrial Recruitment

SOME account of discussions between the Minister of Labour and his predecessor in office and representatives of employers' organizations and the Trades Union Congress General Council on conditions of employment and hours of work in particular industries with reference to unemployment from January 1935 onwards is given in a paper presented to Parliament (Cmd. 5317. London: H.M. Stationery Office. 2*d*.). In the earlier discussions, the Minister directed special attention to the possibility of increasing the number employed by reducing the hours of work, limitation of overtime, rotation of shifts, regular holidays and the effects of such measures on wages and costs. Difficulties in filling vacancies, the actual or potential shortage of trained work-people and the determination of the effective labour supply among the unemployed nominally attached to various industries were also suggested for investigation, and in later discussions the Minister directed special attention to the need for ascertaining accurately the size and nature of labour supply and unemployment in particular industries, as well as in regard to recruitment, training and hours of work.

REPRESENTATIVES of several industries undertook to supplement the available information in such matters, but the Minister directed attention to the lack of balance in the age distribution or in the labour supply or rate of recruitment which exists between different branches of industry. Evidence of present or prospective shortage of skilled labour in some industries was also discussed, including its bearing on the absorption of other workers in the same or in ancillary industries, and the attention of industries was directed to the necessity of considering the new circumstances which would result from the raising of the school-leaving age and the reduction in the number of juveniles who would be available for employment. The discussions have made available a valuable amount of industrial information which should afford a basis for Government or other action if the industries concerned prove unmindful of the responsibilities in regard to the absorption of the unemployed which have thus been brought into prominence, and they illustrate in a striking manner the need for some attempt to handle industrial recruitment on quantitative lines.

The International Commission of Snow

A NEW section of the Association of Scientific Hydrology to deal with the varied problems of snow and ice was organized in time to hold its first meeting in Edinburgh last September a few days before the official opening of the International Congress of Geodesy and Geophysics. A very large number of papers from all over the world were on the programme, and it was felt that the manifold activities of this new Commission will go far to remove the reproach that the study of snowfall, unlike that of glaciation, has been neglected in most countries, even in those which have much snow. The president, Prof. J. E. Church (U.S.A.), who was unfortunately not able to reach Edinburgh in time for the Conference, being detained in Moscow by illness, presented a valuable address on "Snow Surveying: its Methods and Principles", in which he showed the economic importance of the snowfall in the high mountain ranges of the western United States to the semi-arid plains below. The papers will all eventually appear in the *Proceedings of the Association of Scientific Hydrology*. The next meeting of the International Snow Commission will be in Washington, D.C., in 1939. Meanwhile, the various national sections will carry out group work in the problems of snow. In view of the first meeting of the International Snow Commission being held in the Scottish capital, the question of British co-operation in the work naturally came into prominence. A British group of members under the chairmanship of Mr. G. Seligman was formed during the early part of 1936, and by the time of the Edinburgh Conference totalled sixteen, of whom ten attended the Conference. Four papers were presented by the British group, two of which, appropriately to the occasion, dealt with snowfall in the British Isles, one by Captain W. N. McClean on the influence of snow and ice on river discharge in the Scottish Highlands, and the other by Mr. L. C. W. Bonacina on problems of drifting snow in mountainous districts with special reference to the Scottish Highlands.

Index of Geographical Literature

IN 1918, the Royal Geographical Society found it necessary on the grounds of economy to abandon the practice hitherto followed of including in each issue of the *Geographical Journal* a list of additions to the library. These lists from then onwards have been published as separate pamphlets from time to time and distributed to such fellows as expressed a desire to receive them. Up to December 1932, forty-one of these supplements had been published. The entries in these supplements, especially as regards books, atlases and papers, though nominally additions to the catalogues of the Society, in effect comprise a fairly exhaustive list of all geographical literature outside the pages of the *Geographical Journal*. The Society has now published an "Index to Supplements to the Geographical Journal, Vols. 1–5, Numbers 1–41: 1918–1932" (London: Royal Geographical Society. 16*s.*: to fellows, 12*s.* 6*d.*). The terminal date is chosen as coinciding with the termination of the "Fourth General Index" to the *Geographical Journal*. The volume also serves as an index to much of the contents of the annual volumes of the *Bibliographie Géographique Internationale*, for which decennial tables have not recently been issued, the volume numbers in the Index giving the date of publication to within five years.

THE Index which is thus made available is under one alphabet, giving authors and regional names in heavy type. Comprehensive headings are subdivided by italic headings, thus greatly facilitating reference. Thus under British Empire the subdivisions are agriculture and forestry, communications, defence, economics, education, history, mineral resources, politics, population, power, survey, text-books and travel. The lack of a rigid plan of subdivision and the adoption in each large grouping of one suitable for the character of the entries, are useful features. Considerations of space have limited each item to one subject entry. Titles in the less familiar languages are given in the language used in the summaries appended to the articles. Maps and photographs in the Society's collection are omitted, but all atlases are included.

Composition of Scientific Papers

EACH of our two leading medical contemporaries—the *British Medical Journal* and the *Lancet*—includes in the issues of January 2 some helpful suggestions to writers of scientific papers upon styles of composition and typographical conventions. The *British Medical Journal* is given a much more attractive appearance than it has had hitherto by the use of a cover of grey paper with a scarlet design upon it, and the type of the journal has been entirely changed, being now that created a few years ago for the printing of *The Times*. This type is more legible than that formerly used and is particularly suitable for comfortable reading. The *British Medical Journal* announces in the same issue that, in future, the Harvard system of references to scientific literature will be used, instead of numbered references, such as are used in NATURE. Examples are given of these two systems of references to papers. The *Lancet* publishes a special supplement containing advice to authors on the preparation of scientific papers, words and phrases to avoid, summaries, abbreviations, references, and related matters. If these instructions were followed generally, the work of editors would be greatly relieved.

Air Raid Precautions

AIR RAID PRECAUTIONS HANDBOOK No. 4 is entitled "Decontamination of Materials" (London: H.M. Stationery Office, 1936. 6*d.*), and deals with contamination caused by chemical substances capable of giving off poisonous gases. These gases are classified as non-persistent and persistent, the book dealing chiefly with the latter, which include the tear gases (ethyl iodoacetate or *K.S.K.*, and bromobenzyl cyanide or *B.B.C.*) and the blister gases (mustard gas and lewisite). Decontamination of tear gases can be effected by using water, earth or a mixture of glycerin and caustic soda according to circumstances. Decontamination due to blister gases includes ventilation, hosing with water, removal by solvents, several methods of applying bleaching powder, immersion in boiling water, covering with earth, and destruction of the contaminated article by burning. In all cases, identification of the poison gas should precede attempts towards decontamination, and the latter should therefore be carried out only by persons specially trained and thoroughly protected. Appendixes in the manual deal with the equipment of a decontamination squad and methods of dealing with road surfaces, the structures of buildings, household articles and vehicles.

Colorado Potato Beetle

IN consequence of the spread of the Colorado potato beetle from France and Belgium into Germany and Luxemburg, the Ministry of Agriculture and Fisheries has made an order "The Importation of Plants (Amendment No. 2) Order of 1936" regarding plant imports into Great Britain. The Order imposes restrictions on the importation from Germany and Luxemburg of certain kinds of horticultural produce as from January 11. The restrictions are similar to those already in force with respect to like produce from France and Belgium. The provisions of the order require a certificate in one of two forms to accompany living plants, potatoes, raw vegetables and cider apples imported from the countries mentioned. Copies of the Order (S. R. and O. 1936, No. 1288), price 1*d.* each net, may be obtained from H.M. Stationery Office, Adastral House, Kingsway, London, W.C.2.

Campaign against Noise

THE Leningrad Institute for the Protection of Labour is doing much useful work in combating the noise of machinery in Soviet factories. Some two hundred silencers of special design have been fitted to the automatically driven lathes of Leningrad factories manufacturing electrical apparatus. It is claimed that these silencers reduce the noise of the machines to the loudness of the normal human voice. The Institute is also carrying out experiments to reduce the noise of machinery at other types of works and factories and on the motor-ships of the Black Sea. During the past year the Institute has received more than twenty different designs for silencers from Soviet engineers and factory workers.

Earthquake in Kent on December 29

AT about 1.30 p.m. on December 29, a very slight earthquake, accompanied by a rumbling sound, was felt in the east of Kent. The villages in which it was observed (Adisham, Nonington, Snowdown, etc.) are close to the centre of the area disturbed by the much stronger Canterbury earthquake of November 27, 1776, that was felt with some intensity (about 6, Rossi-Forel scale) at Canterbury, Sandwich, Deal, Dover, Folkestone and Ashford, and, though very slightly, at Calais, thirty-four miles from the centre.

Sands, Clays and Minerals

The most recent issue of this journal (**3**, No. 1, November 1936. A. L. Curtis, Westmoor Laboratory, P.O. Box 61, Chatteris, Cambridgeshire, price 3*s*. 6*d*.) has been considerably enlarged and contains articles covering a wide range of subjects. Topics of economic importance dealt with in this number include nickel, silica sand as a basis for phosphate deficiency tests on lettuce, minerals of Brazil, titanium oxide in industry, boron, soils, industrial water supply, barytes in Greece, mining resources in Tanganyika, etc. The articles are written by authors actually engaged in research on the subject, thus making them authoritative. A contribution by A. L. Curtis on the history and activities of the Fuel Research Station at Greenwich makes interesting reading. The journal is attractively produced, and is an excellent source of information, especially for mineralogists, chemical engineers and other men of science and technology concerned particularly with the mineral resources of the British Empire.

Physical Society's Exhibition Catalogue

The Catalogue of this Exhibition, which was open on January 5–7, now covers nearly 200 pages and is well provided with indexes of exhibitors and of apparatus, plans, stall numbers on the outer top corner of each page, marks for new apparatus and for demonstrations, all of which help a visitor to find readily what he wants particularly to see. Illustrations are plentiful, but many are limited to views of the outsides of the boxes containing the instruments, while the interest of the visitor is more often centred in the principle of the instrument itself. The division of the catalogue into two sections devoted respectively to trade exhibits and research and educational exhibits is maintained, and the award of prizes to apprentices for exhibits of work done is continued. A new announcement is made of the intention of the Council to apply part of the legacy bequeathed to the Society by the late Herbert Spencer, for grants to fellows for the purchase of special research apparatus. The order of the stands in the catalogue and their stand numbers are arranged geographically to facilitate reference, and the asterisk which now marks a new exhibit in the body of the catalogue might with advantage in future years appear also in the apparatus index.

Announcements

Sir William Bragg will open the new extension to the Research Laboratories of the British Association of Research for the Cocoa, Chocolate, Sugar Confectionery and Jam Trades and the British Food Manufacturers' Research Association at 2 and 4, Dalmeny Avenue, Holloway, London, N.7, on January 19. There will be a reception from 3 until 6 p.m.

The King has been pleased, on the recommendation of the Secretary of State for Scotland, to approve the appointment of Prof. Lancelot Hogben, professor of social biology in the University of London, to be regius professor of natural history in the University of Aberdeen, in succession to Prof. James Ritchie. Prof. Hogben was formerly assistant professor of zoology in McGill University, Montreal, and professor of zoology in the University of Cape Town.

Mr. N. B. Kinnear and Dr. H. A. Baylis have been appointed to deputy keeperships in the Department of Zoology of the British Museum (Natural History). Mr. Kinnear was born in 1882 and is a great-grandson of Sir William Jardine, the early nineteenth century naturalist. He is well known as an ornithologist, and prior to his appointment to the Museum sixteen years ago was in charge of the Bombay Natural History Society's Museum. He is the editor of the *Bulletin of the British Ornithologists' Club*. Dr. Baylis was born in 1889 and was educated at Epsom College and Jesus College, Oxford. He entered the Museum in 1912, and has specialized throughout his career in parasitic worms. He is the author of many scientific papers on this subject, and has built up a very large collection of these organisms, of which, before his time, the Museum possessed only a few specimens.

Prof. P. M. S. Blackett will deliver the Cantor Lectures before the Royal Society of Arts on January 18, 25 and February 1. The subject of the lectures will be "Cosmic Rays".

The Sir Halley Stewart Trust has placed at the disposal of the Medical Research Council a sum of £500 a year for three years for a senior fellowship tenable in the Neurological Research Unit at the National Hospital for Nervous Diseases, Queen Square, London. This arrangement has been gratefully accepted by the Council with the concurrence of the Medical Committee of the Hospital, and the position has been awarded to Dr. Joseph Doupe.

The seventy-first volume of the *Journal of Anatomy* is termed the "Elliot Smith Volume" and is dedicated to Sir Grafton Elliot Smith (see p. 57). Appropriately enough, Part 1, which was issued last October, contains his portrait as a frontispiece and commences with a biographical sketch of his early career by Prof. J. T. Wilson, who, in his early years in the Challis chair of anatomy in the University of Sydney, included Elliot Smith among his students.

Mr. B. D. W. Morley, of Holy Trinity Vicarage, Madeira Road, Bournemouth, Hants, asks anyone who has been studying, or has at any time studied, communication among ants, to get in touch with him.

Will Mr. Paul Molde, of Copenhagen, who sent a communication to the Editor entitled "On the Atomic Structure of Living Matter : A Biole Hypothesis", kindly communicate his address.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 73.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Ancestors of the Diptera

IN a previous communication to NATURE some years ago (May 18, 1929) I gave a short description of a remarkable genus *Permotipula*, represented by a complete forewing from Warner's Bay, N.S.W., and of Upper Permian Age. Although very primitive by comparison with existing types of Diptera, this wing was regarded by me as being definitely Tipuloid and lying well within the order. I added the following remarks: "The wing is of the greatest interest, because any student of venation would classify it as dipterous and nothing else, and yet *we do not know whether the insect to which it belonged had four wings or only two*! Also, it is the oldest known dipterous type of wing by many millions of years."

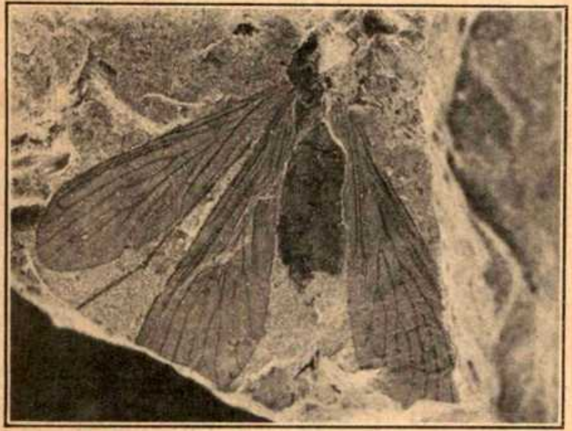

Fig. 1.

NEARLY COMPLETE SPECIMEN OF A PROTODIPTERON, ALLIED TO *Permotipula*, FROM THE UPPER PERMIAN OF WARNER'S BAY, N.S.W. LENGTH OF HINDWING ABOUT 5 MM.

It has always been my hope that, one day, a complete specimen of this insect, with its wings conveniently outspread, might be found at Warner's Bay by some lucky stroke of fortune. After many visits to that locality, and after the discovery of a fair number of dipterous wings, more or less allied to *Permotipula*, but, for the most part, too crumpled by the action of water to add much to our knowledge, I had almost begun to despair of ever finding a complete insect or of solving the problem of the nature of the hindwing in Permian times. But, on a recent visit, I had the good fortune to discover, right on the very edge of a large block of rock, an almost complete specimen of a genus extremely close to *Permotipula* (Fig. 1). This specimen had been preserved with the two wings on the right side superimposed in the normal way for a stegopterous insect, but, on the left side, the hindwing had slipped under and forward of the fore, so that the venations of both wings can be clearly made out, the only missing portion being the extreme apex of the forewing. We thus discover the remarkable fact that, apart from size, the forewings and hindwings are almost exactly alike; *if the hindwing had been found fossilized by itself, it would almost certainly have been considered to be the forewing of a primitive Tipuloid Dipteron.* In order to show this more clearly, a drawing of the separate hindwing is shown in Fig. 2, with the names of the veins marked on it.

It can be said at once that the venation is very close to that of the living family Tanyderidæ, though the fossil form is slightly in advance of the living types owing to the great reduction of the primitive fork of R_{2+3}. Further, we note the remarkable fact that the forewings and hindwings are attached to the thorax very close together, so that we are bound to conclude that the metathorax was already greatly reduced in the fossil form, in spite of the fact that the hindwing was large and fully functional. Finally, in view of the fact that a true Dipteron, closely allied to the Tanyderidæ, has now been discovered in the upper Triassic beds of Mount Crosby, Queensland, we are able to state definitely that the loss of the hindwing occurred during the period between the Upper Permian and the Upper Trias. But we are still as much in the dark as ever concerning the manner in which the reduction to a halter took place.

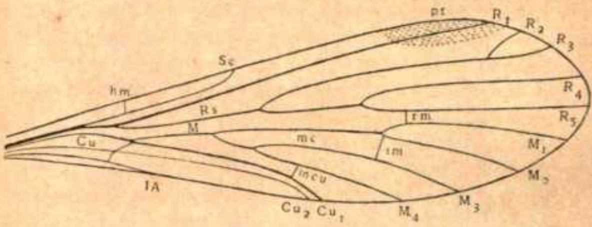

Fig. 2.

VENATIONAL SCHEME OF HINDWING OF THE SPECIMEN SHOWN IN FIG. 1. THE VENATION OF THE FOREWING IS SIMILAR, BUT *Sc* IS CONSIDERABLY LONGER.

As the new fossil cannot be placed in the order Diptera, and as it is clearly a specialized Paratrichopteron possessing a reduced anal area and only a single anal vein, I propose to term the group to which it belonged Protodiptera. The evolutionary series leading to the Diptera is now as follows:

(1) Order MECOPTERA (s.str.), family PERMOCHORISTIDÆ.

Rs with four or more branches, *M* with five or more branches, usually six; three anal veins present. All four wings present.

(Lower Permian to Upper Permian.)

(2) Order PARATRICHOPTERA.

Both *Rs* and *M* with four branches only, arranged dichotomically; three anal veins present. All four wings present.

(Upper Permian to Lias.)

(3) Order PROTODIPTERA.

Rs with four or three branches; *M* with four branches; anal veins reduced to two or one only. Cu_2 becoming obsolete and approaching Cu_1 closely. All four wings present.

(Upper Permian.)

(4) Order DIPTERA.

Rs and *M* both archetypically with four branches, but many forms show reduction. Anal veins at most two, generally only one. Cu_2 obsolescent or obsolete, usually indicated merely by a faint groove just below Cu_1. Hindwing reduced to a halter or balancer.

(Upper Triassic to Recent.)

In the above evolutionary sequence, it is important to notice that the first cubitus (Cu_1) is a simple, unbranched vein right through from (1) to (3) and also for the earliest types within the Diptera, but that, soon after the establishment of this latter order, the capture of vein M_4 by way of the cross-vein *mcu* produced a large number of forms (most of the recent Diptera) in which, as in the Trichoptera and Lepidoptera, the vein Cu_1 appears to be forked.

As the gaps in the fossil record are now all but filled, it is impossible to continue to maintain the Paratrichoptera and Protodiptera as fundamentally distinct from true Mecoptera. I therefore consider it advisable to treat these groups henceforth as specialized suborders of an enlarged order Mecoptera, to which all the four-winged forms with a simple Cu_1 are now relegated.

R. J. TILLYARD.

Canberra, Australia.
Oct. 25.

Combustion Levels

THEORETICAL flame temperatures and explosion pressures calculated upon the basis of the quantum specific heats (which have been shown to be substantially correct[1]) are never reached in flames and explosions. Even when measurements of the actual flame temperatures and explosion pressures are postponed for such length of time as to make it certain that chemical combination is complete and full allowance is made for heat loss, there is still a defect of the measured temperatures and pressures below the calculated—a defect which remains constant in amount during the whole of this time. In short, in flames and explosions, definite ceiling temperatures and ceiling pressures are reached which fall short of the calculated temperatures and pressures.

The defect of the ceiling flame temperatures and explosion pressures below the calculated has been shown[2] to be dependent upon the nature of the combustible gas, the nature of the diluent gases and notably the pressure at which combustion takes place—the higher the pressure the less the defect.

The defect in the explosion pressures is much less than the defect in the flame temperatures. (In ordinary flames the defect of temperature amounts to many hundreds of degrees centigrade.) A completely satisfactory correlation is obtained, however, if it be assumed that the pressure that really matters is the instantaneous pressure in the flame front[3].

Demonstration of the correctness of this view is provided by some photographic studies by Bone and Frazer of flame travel in long tubes closed at one end only—the firing end. Two of these will suffice for our purpose, namely, Figs. 1 and 4, plates 13 and 14, *Phil. Trans. Roy. Soc.*, A, **230**, 363 (1931). These relate to flame travel in $2CO + O_2$ mixtures and are reproduced here in Fig. 1 through the courtesy of Prof. W. A. Bone and Mr. R. P. Frazer.

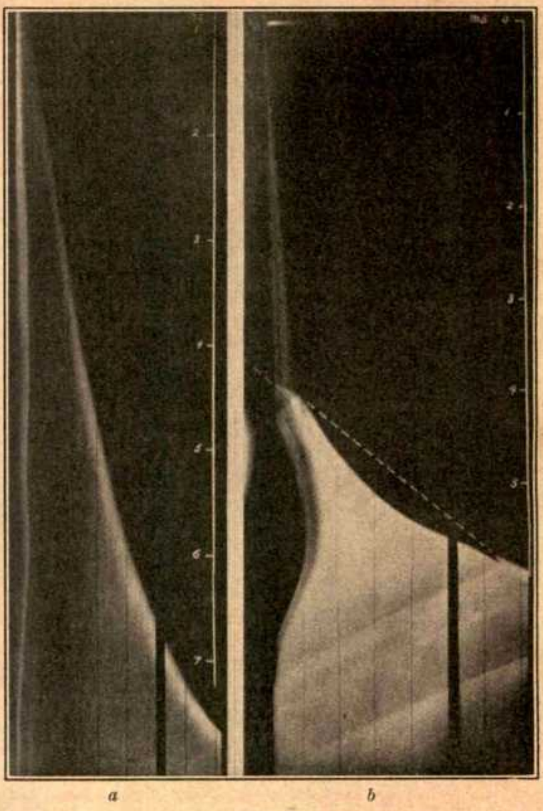

Fig. 1.

It will be seen from Fig. 1, *a*, that not only the flame front luminosity, but also the intensity of the after-glow in the flame gases left behind, increases with distance of travel of the flame front and therefore with pressure in the flame front. The intensity of the after-glow has been shown to be dominated by the temperature of the flame gases[4] and it may fairly be inferred that the temperature of the flame gases resulting from the combustion of any given inflammable mixture increases as the pressure in the flame front increases. This is very vividly demonstrated in Fig. 1, *b*, in which the pressure in the flame front after travelling some short distance is artificially increased by an overtaking shock wave. It will be seen that not only is there a marked and sudden increase in the luminosity of the flame front but in the after-glow also.

The combination of the mixture $2CO + O_2$ is complicated by dissociation in the flame gases, but this does not affect the interpretation of the photographs given above.

It has been suggested that a long-lived and stable form of latent energy resides in flame gases (as long as they remain in the homogeneous phase) which is probably located in metastable molecules of some kind or other formed in the flame front[5]. For many purposes the term 'combustion level' is a more convenient one, by which is meant the ratio of the energy which can be accounted for in flame gases on the assumption that they are normal gases to the heat of combustion of the inflammable gaseous mixture.

Measurements show that the combustion level in ordinary flame gases (which are assumed to be similar to those left behind the initial slow movement of flame during its passage through inflammable mixtures at atmospheric pressure) is of the order of 72 per cent in carbon monoxide – oxygen – argon mixtures, 80 per cent in carbon monoxide – air mixtures, 83 per cent in methane – air mixtures and 85 per cent in acetylene – air mixtures[6]. The combustion level in flame gases left behind a 'detonating' flame front would approach 100 per cent owing to the high pressure in the flame front.

The combustion level in any given mixture may apparently have any value between some lower limit and a higher limit approaching 100 per cent. The not very intense luminosity of many oxy-gas flames suggests much lower combustion levels than those measured in air-gas flames.

Wave Mechanics of Couples (Neutron – Neutrino)

FERMI considers the β-decay as the transition of a 'heavy' particle from the neutral state (neutron) into a charged state (proton) with simultaneous emission of two light particles (electron, neutrino). I consider correspondingly the β-decay as a special case of processes in which a *couple of particles* (neutron – neutrino) are involved. The principal feature of these processes is the fact that the rest-mass of the single particle is not conserved, but only that of a couple as a whole. The accepted methods of quantum mechanics do not apply to this case; some new principle is required.

I reject the idea of introducing rest-mass as a *new* observable, since there is no variable known on which the corresponding operator should be applied. I shall show that a straightforward generalization of Dirac's method leads to a consistent theory of a couple of particles.

Let the co-ordinates of the two particles (in four dimensions; $x_4 = ict$) be x_k, X_k ($k = 1, 2, 3, 4$), the corresponding momenta $p_k = 1/i\ \delta/\delta x_k$, $P_k = 1/i\ \delta/\delta X_k$. Let $\gamma_1, \gamma_2, \gamma_3, \gamma_4$ be four Dirac matrices, $\gamma_k\gamma_l + \gamma_l\gamma_k = 0$ ($k \neq l$; $k, l = 1, 2, 3, 4$), chosen as real ($\gamma_k^+ = \gamma_k$) and normalized ($\gamma_k^2 = 1$).

Then the quantities $\gamma_{kl} = i\gamma_k\gamma_l$, $\Gamma = -\gamma_1\gamma_2\gamma_3\gamma_4$, $\Gamma_k = i\Gamma\gamma_k$ are also real and normalized. We construct the most general operator Ω which is (1) a real number in the hyper-complex algebra of the γ's, (2) linear in the p_k, (3) linear in the P_k, and for which (4) $\Psi^+\Omega\Psi$ is a relativistic invariant ($\Psi(x,X)$ is a wave function with four components forming a column, Ψ^+ its adjoint, forming a row); the form of Ω is uniquely determined, as

$$\Omega = A + B\,\Sigma_k\gamma_k p_k + C\,\Sigma'_{kl}\gamma_{kl}(p_k P_l - p_l P_k) + D\,\Sigma_k\Gamma_k P_k + E\Gamma,$$

where A, B, C, D, E are real constants.

In analogy with Dirac's theory, we subject Ω further to the

Postulate: Ω^2 is free from spin quantities.

Since Ω^2 must be invariant, it must have the form

$$\Omega^2 = A^2 + B^2\Sigma_k p_k^2 + C^2\Sigma'_{kl}(p_k P_l - p_l P_k)^2 + D^2\Sigma_k P_k^2 + E^2.$$

The analysis of this postulate leads to the

Theorem: The necessary and sufficient condition for Ω^2 being free from spin quantities are the relations

$$A = 0,\ BD - CE = 0.$$

They reduce the five constants to three. As the dimensions of Ω do not matter, we can choose one constant as unity, say, $E = 1$. For the only two arbitrary constants left we introduce the notations $B = \lambda_0$, $D = \Lambda_0$ (Compton wave-lengths); then $C = \lambda_0\Lambda_0$, and

$$\Omega = \Gamma + \Lambda_0\Sigma_k\Gamma_k P_k + \lambda_0\Sigma_k\gamma_k p_k + \lambda_0\Lambda_0\Sigma'_{kl}\gamma_{kl}(p_k P_l - p_l P_k).$$

Here p_k and P_k have to be replaced by $p_k + \alpha\Phi_k$ and $P_k + \beta\Phi_k$, where the electromagnetic potentials Φ_k are symmetric functions of $x_k - X_k$ and α, β operators which transform any function of x_k, X_k into its symmetric resp. antisymmetric part. Then the wave equation can be derived from the variation principle

$$\delta\int\Psi^+\Omega\Psi\,dx\,dX = 0.$$

For treating an assembly of particles one has to consider Ψ, Ψ^+ as observables (non-commuting quantities), and to apply the method of second quantization.

I have proved that this theory represents the electromagnetic forces and the nuclear 'exchange' forces by the same formalism.

Interaction by Resonance of Radio Waves

DR. MARTYN and I have already given a quantitative theory of the phenomenon known as the interaction of radio waves[1]. This theory has been found to be in good agreement with observation, and has in particular led to conclusions about the acoustic distortion of the impressed modulation which the subsequent observations of van der Pol and van der Mark adequately confirmed. There is, however, in this theory an inaccuracy of which I became aware about a year ago while engaged in a related investigation, and which at first sight appears of no great importance.

On revising the theory and establishing it on a more rigorous foundation, however, an unexpected and interesting consequence emerged, namely: that in regard to the amount of modulation which a wave W can impress on another wave W', there may occur a notable degree of *resonance* when the angular frequency ω of the wave W passes through the value Ω, where $\Omega = He/m$ is the 'gyro-frequency' corresponding to the total terrestrial magnetic force H in the part of the ionosphere concerned.

The theory also deduces, from the generally accepted body of knowledge about the propagation of radio waves and about the motions of electrons in air, that a radio-station the wave of which has an angular frequency within about 5 per cent of the local gyro-frequency can produce observable interaction with suitable medium and long waves when this station radiates power at the rate of about one or two kilowatts.

Among conditions favourable to the occurrence of such resonance-interaction the following are indicated: The received sky wave W' should be reflected from a region of the ionosphere the horizontal projection of which lies within about 200 kilometres from a 'gyro-station' and should have a minimum wave-length λ_m which depends on the distance D, between the radiator of W' and the receiver, somewhat as follows:

D (km.)	400	600	1,200
λ_m (metres)	2,000	1,200	500

These estimates of λ_m are made for the average nocturnal circumstances which Martyn[2] supposes to occur in the lower part of the E-layer, and much lower values of λ_m may be expected to correspond to certain abnormal conditions which are known to occur occasionally[3].

After reaching these conclusions, I looked over some old issues of *World Radio* and was agreeably surprised to find the following report[4] by the secretary of the World Radio Research League: "Mr. L. Thompson, of Ambleside, Westmorland, reports a background of Dublin (222·6 m., 0·2 kW.) on Athlone (531 m., 60 kW.). Here is apparently a shorter-wave affecting a longer-wave station. This was observed by Mr. Thompson on another occasion".

From such magnetic data as are available to me at present, the resonant wave-length in the E-layer half-way between Athlone and Ambleside is estimated to be about 232 metres, which differs by only 4 per cent from the wave-length of Dublin's radiation. Also the power radiated at the time of Mr. Thompson's observations might well have been 0·5 kilowatt, for that is the power officially assigned to Dublin's station in the issue of *World Radio* published two weeks after that in which the observations were reported.

The fact that the radiation interfered with has a wave-length as low as 531 metres leads to the conclusion that in those parts of the E-layer concerned with the interaction, a gradient of ionization existed which considerably exceeds those adopted by Martyn[2].

A survey of contemporary European and American wave-lengths and powers shows that among others the following broadcasting stations may be found to produce by resonance-interaction observable backgrounds in the waves received from other [illegible] Monte Ceneri (257·1 m.), Freiburg (25[illegible] (251), Lille (247·3), Radio Marco[illegible] (241·9), Saarbrücken (240·2[illegible] Klagenfurt (231·8), Vorarlb[illegible] Kiel (225·6), Hano[illegible] of NATURE have already observed this interaction by resonance, or can observe it in connexion with any of the stations given above.

If observations could be made with a station the frequency of which may be varied about the gyro-frequency, they could be used to determine at least two important quantities, namely, the values in the E-layer of the electron collision frequency and of the earth's magnetic force. In Australia there are unfortunately no stations suitable for this purpose, but I hope shortly to visit Europe and would be glad to have reports, on any relevant observations that may be made, addressed to me at the Queen's College, Oxford.

A fuller discussion of the theory will be published elsewhere in due course.

Radio and Magnetic Observations at North-East Land during the Total Solar Eclipse of June 19, 1936

RADIO observations on the solar eclipse of June 19, 1936, were made by the Oxford University Arctic Expedition 1935–36 in North-East Land at 80° 23′ N., 19° 31′ E. in accordance with the programme arranged by a sub-commission of the U.R.S.I. One complete record showing the relationship between the equivalent height of reflection and the frequency of the exploring wave was obtained in steps of 0·2 mc./sec. The records, each of which took ten minutes to secure, were centred on each hour and half-hour from 03.30 to 07.30 G.M.T. on June 18, 19 and 20, 1936 (Fig. 1). Short-period variations would not therefore be observed.

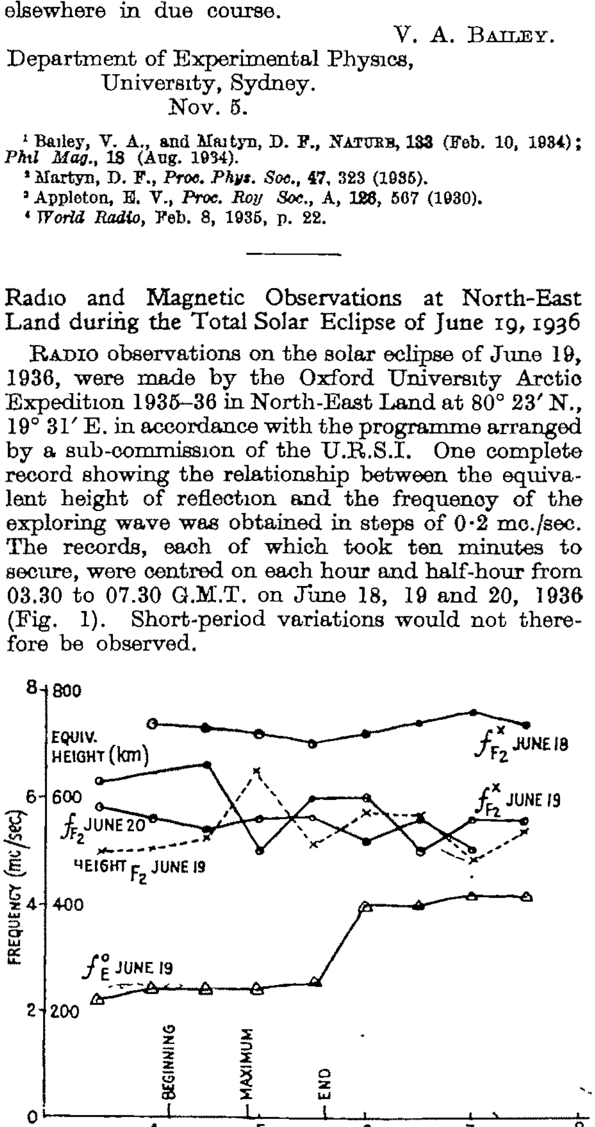

Fig. 1.

[illegible]ipse began at 04.10, was a maximum, 25 per [illegible]ea, at 04.54 and ended at 05.40. At the in the declination traces (Fig. 2), and this fact makes it difficult to interpret the exact effects of the eclipse. The magnetic disturbance is reported on a world-wide scale and appears to have begun about 17.45 G.M.T. on June 18. The most significant facts emerging from our observations are:

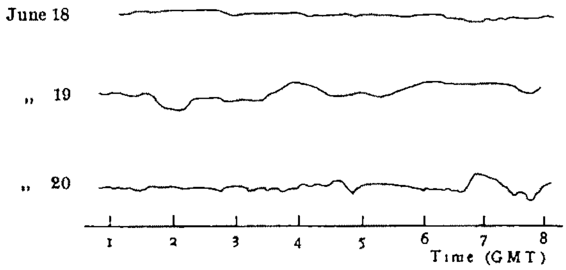

Fig. 2.

(1) On June 18 and 20, f^0_E rose fairly steadily from 03.30 to 07.30, but on June 19 it was below the average before and during the eclipse, and rose suddenly to a value above the average of June 18 and 20 immediately after the eclipse. Previous eclipse results have shown that f^0_E decreases when the ultra-violet light is cut off, but it is probable that in our case it was from the abnormal Region *E* that echoes were obtained. The persistence of echoes from the region beyond the critical frequency makes the determination of the exact value of this frequency difficult.

(2) On June 18 and 20 the ionization density of Region *F* increased as the day advanced. On June 19, however, after 05.30 it became vestigial and remained so until 07.30, but the ionization had increased again by 10.30, local noon.

(3) The height of Region F_2 was greater on the morning of the eclipse than on the other two mornings. At the time of maximum eclipse, it showed a marked increase in height, and $f^0_{F_2}$ decreased appreciably, showing a marked minimum.

The 2·73 μ Absorption Band of Fused Silica

DR. D. G. DRUMMOND, in commenting[1] upon his own and our suggestions[2] that the 2·73 μ band of fused quartz is possibly produced by dissolved carbon dioxide, suggests that it would be of interest to know whether the quartz specimens which we used were prepared without contact with carbon. This interest arises from the fact that in none of our specimens did we find a trace of the band in question, whereas other investigators always have found such a band. Inasmuch as we had made a particularly careful study of a 5 mm. plate furnished us by the Hanovia Chemical and Manufacturing Company, of [illegible] N.J., we wrote to this company and wish [illegible] them as follows: "Quartz specimens of o [illegible] facture are prepared between carbon bl [illegible] [illegible] with flames containing carb [illegible] some methods of manufacture must be other than carbon dioxide. We made observations on several other samples, some of which were probably furnished by other companies, but we are unable to make a complete trace of the records of purchase.

In our previous letter[2], we gave our reasons for believing that the impurity involved may be water-vapour. Evidence for the existence of either carbon dioxide or water vapour could doubtless be obtained either by Dr. Drummond or by some other experimenter possessing a fused quartz specimen several centimetres in thickness which shows the 2·73 μ band. This could be done by locating higher overtone bands in the region of waves shorter than 2·7 μ. In support of the water vapour hypothesis, we wish to point out that if this appeared as an impurity to the extent of only a few tenths of one per cent, it would account for the depths of the 2·73 μ absorption band even in the cases of those earlier investigations in which the bands appeared with considerable intensity.

[1] Drummond, NATURE, 138, 248 (1936)

[2] Ellis and Lyon, NATURE, 137, 1031 (1936).

THE note by Drs. Ellis and Lyon appears to leave no longer tenable the hypothesis of carbon dioxide impurity as the cause of the 2·73 μ absorption band in fused silica. They suggest searching for higher overtone bands as a method of identifying the impurity. From my published curves[1] in the shorter wave-length region, it will be seen that though the 2·73 μ band appears with considerable intensity in Section *C* (29·85 mm. thickness) the water vapour bands near 1·36 μ and also 1·87 μ are absent, though they might have been expected with intensities of the order of 10–20 per cent. The water vapour band near 6 μ would not be expected to show, even if present, in Section *H* (0·109 mm. thickness), since here the thickness of material is much too small.

I should mention that in curve *A*, in my paper quoted, the resolving power was too low to decide whether narrow bands were present, the great length of this specimen preventing the utilization of the full resolving power of the apparatus.

I have observed this 2·73 μ band also in emission from hot fused silica, and intend publishing a note to describe this work.

Mechanism of the Diastole of Contractile Vacuoles

IT is still not known what causes the passage of fluid from the cytoplasm into the contractile vacuole of a protozoan. In a recently published paper[1], [illegible] claimed that the rate of this "infiltration" [illegible] the vacuole will be proportional, among [illegible] the difference between the hydro- [illegible] cytoplasm (which is maintained [illegible] and the colloid osmotic [illegible] former tending to

Under an inversion OP.OP′ = K, if P is on a sphere with centre C and radius r, bend $b = 1/r$, then P' is on a sphere with bend

$$b' = b(OC^2 - r^2)/K.$$

If P is on a plane (directed of course) at a distance δ from O, then P' is on a sphere with bend $b' = 2\delta/K$.

Hence

$$Kb'_1 = OC_1^2 - 1$$
$$K(b'_2 + b'_3) = 4$$
$$Kb'_4 = OC_4^2 - 1$$
$$Kb'_7 = OC_7^2 - 1.$$

Also since C_1 is the mid-point of C_4 and C_7 and at a distance ± 2 from them,

$$OC_4^2 + OC_7^2 = 2(OC_1^2 + 4).$$

Hence, in general,

$$b'_4 + b'_7 = 2(b'_1 + b'_2 + b'_3).$$

Similarly,

$$b'_4 + b'_6 + b'_8 = b'_5 + b'_7 + b'_9 = 3(b'_1 + b'_2 + b'_3).$$

The argument in this form is only good for a flat space.

Points from Foregoing Letters

THE discovery of a fossil insect (a protodipteron from the Upper Permian of Warner's Bay, N.S.W.) which throws light on the evolution of two-winged insects (Diptera) from four-winged ones, is reported by Dr. R. J. Tillyard. The author gives a list of the stages which have led to the evolution of Diptera during the period between the Upper Permian and the Upper Trias.

To explain the discrepancy between the temperatures and pressures observed in gaseous explosions (neither of which reach the calculated values), Prof. W. T. David assumes that the effective pressure is the instantaneous pressure in the flame front. He reproduces two photographs of flame travel by Bone and Frazer, from which he infers that the temperature of the flame increases as the pressure in the flame front increases. Prof. David introduces the concept of 'combustion level'—the ratio of the energy which can be accounted for in the flame gases, to the theoretical heat of combustion.

By a generalization of Dirac's method, Prof. Max Born develops a theory of the emission of electrons in atomic transformations, as a special case of processes in which a pair of particles (neutron and neutrino) is evolved, the principal feature being that the rest-mass of a single particle is not conserved, but only that of the pair as a whole. The theory represents the electromagnetic forces and the nuclear 'exchange' forces by the same formalism.

Further developments of the theory of the interaction of radio waves leads Prof. V. A. Bailey to the conclusion that a notable degree of resonance may occur when the angular frequency of the wave which causes interaction approximates to the 'gyro-frequency', corresponding to the total terrestrial magnetic force in the part of the ionosphere concerned. He further deduces that observable interaction may be caused by a station which radiates power at the rate of 1 or 2 kilowatts when its frequency is within 5 per cent of the relevant gyro-frequency. A list is given of stations which may be found to produce resonance-interaction.

Radio and magnetic observations made during the solar eclipse last June at North-East Land are reported by A. B. Whatman and R. A. Hamilton. The ionization density of the F region became very small during the eclipse. The f_E^0 layer of the ionosphere was below the average before and during the eclipse but rose above the average after the eclipse, and the height of the $f_{F_1}^x$ layer was at a minimum during the eclipse while that of the F_2 region increased.

The origin of the absorption band at 2·73 μ in certain specimens of fused silica remains unexplained. Dr. J. W. Ellis and Dr. W. K. Lyon state that a specimen which did not show this absorption band nevertheless probably contained carbon dioxide, so that carbon dioxide cannot be the cause of the absorption band. On the other hand, Dr. D. G. Drummond reports that a specimen which shows the band at 2·73 μ does not show the water vapour bands at 1·36 and 1·87 μ, which rules out water as the source of the former band.

The expansion of the contractile vacuoles of Protozoa cannot be explained, according to Dr. J. A. Kitching, merely by reference to the hydrostatic pressure of the cytoplasm. Experiments on freshwater Protozoa give further support to the osmoregulatory theory, which implies an active secretion at the vacuolar surface.

Dr. E. Ashby and L. C. Luckwill find that when a dwarf strain of the tomato is crossed with a tall variety of a nearly related species (*Lycopersicum racemigerum*), the growth-ratio between stem-weight and leaf-weight in the hybrid is not intermediate between that of the parents but is inherited in the manner of a 'simple dominant'. In this it resembles other physiological characteristics, namely, the efficiency index, the assimilation rate and the respiration rate.

A marked growth response of plants to permanganates has been further investigated by M. E. Webster and Dr. I. M. Robertson by means of controlled pot experiments with the cactus, *Opuntia Leucholricha*.

Dr. E. G. Cox, A. J. Shorter and Dr. W. Wardlaw state that X-ray studies of several quadricovalent derivatives of bivalent tin and lead show that those metals can possess a planar distribution of four valencies. As tin and lead with a principal valency of four have a tetrahedral distribution of bonds, it appears that in these cases, as with copper, silver and platinum, the principal valency determines the arrangement of their atoms.

Dr. J. Newton Friend suggests that realgar (arsenic disulphide) found with Roman remains at Wookey Hole, Somerset, had probably been imported for medicinal purposes.

Dr. F. Morley gives a formal proof of the hexlet, which should be read in conjunction with Prof. Soddy's article (p. 77) and the note on p. 62.

Research Items

Races on the North-West Frontier of India

THE physical anthropology of the inhabitants of central Asia is known only from the measurements taken by Sir Aurel Stein on his various journeys of exploration. To three series already recorded a fourth has now been added—measurements of the inhabitants of the valleys of Hunza in the Gilgit Agency and Swat in the North-West Frontier Province. These have been subjected to statistical analysis by Dr. G. B. Morant (*J. Roy. Anthrop. Inst.*, 66, Pt. 1). The series from the Swat Valley consists of 54 men of Torwal (classified on linguistic grounds as Dards) and 25 Pathans. The people of Hunza, which lies at the junction of India, Chinese Turkestan and Afghanistan, are the people speaking Burushaski, a tongue related to no known language. Part of their valley has been occupied by Wakhi. 75 Hunza men and 25 Wakhi were measured. The principal measurements are as follows: Torwali, cephalic index 75·3, nasal index 68·1, stature 1,688·8; Pathan, cephalic index 76·9, nasal index 72·0, stature 1,654·8; Hunza, cephalic index 79·6, nasal index 71·4, stature 1,688·1. Dr. Morant from his analysis of the material concludes that the Pathans differ from the Torwali in having smaller head-lengths, facial height and stature and relatively broader faces and noses. Between the Hunza and Torwali the significant differences are the head length, head breadth, and cephalic index, nasal height and nasal breadth. The men of Hunza have the smaller head length and the larger head breadth, so that the mean cephalic index is apparently the larger and nasal height and breadth the smaller. The Hunza-Pathan series differs significantly in head breadth, cephalic index, nasal height, nasal breadth, stature and facial height. The two elements in the Swat valley are more nearly akin to one another than either to the men of the Hunza valley. The Pathan is less variable than the Torwali and both are less variable than the Hunza—a remarkable and unexpected result.

Ivory Arrow-Straightener from Alaska

AN ivory arrow-straightener of considerable interest has recently been presented to the British Museum (Bloomsbury) by the Trustees of the Christy Fund. It has been described and figured by Mr. A. Digby (*Brit. Mus. Quarterly*, 11, 1). It resembles a spanner with an oblique rhomboid hole at one end. The handle terminates in a bear's head, the eyes of which are inlaid with wood; while at the other end beyond the hole are two smaller bear's heads. On all four surfaces small figures have been scratched with a stone point, or perhaps an iron nail. They depict either individual animals, seals and caribou, or scenes from Eskimo life. The back shows large and small deer, two of which leave footprints, an unusual feature in Eskimo art, and a hunting scene on the right-hand edge. A man paddling a kayak and flourishing a lance chases five caribou, while behind him are the floating carcases of three more. On one edge of the left-hand side is a similar scene. These scenes depict a method of hunting frequently adopted in autumn. The other figures on this side are a lone caribou, a row of dancing figures, three conical tents, such as are used in summer, and an Alaskan sledge. On the other side is a village scene showing summer tents, drying frames and human figures. A man is shooting at a row of birds represented by crosses. The front, or lower surface, is covered with figures, which may be seal or walrus. There are two human figures; at the lower end is the figure of a crawling man; and at the other end a man attacking a seal. The straightener is probably a tally recording the kill of the owner. The date is difficult to determine, but comparison with a drill bow in the Barrow Collection suggests the beginning of the nineteenth century.

Physiology of Flute Playing

THE rumour that players of wind instruments run the risk of respiratory diseases is still current in musical circles, although there has never been much scientific foundation. Jagic and Lipinfr (Wien, *Klin. Wschr.*, 32, 683 and 714; 1919) examined medically (including X-ray) 46 professional wind players who had played 4–5 hours a day for periods varying from 10 to 50 years. They found no case of emphysema or other lung disease among them. Dr. J. Roos ("The Physiology of Playing the Flute", *Arch. Néerland. Phon. Exp.*, 12, 1; 1936) reports data of interest bearing on the same question. Three professional flautists were submitted to a number of physiological tests while playing. The air pressure exerted was measured, in relation to the pitch of the note, and its loudness, on both of which factors it depends. The range of pressures was of the same order as those found by other workers for singing. The mechanism of giving air at well-regulated pressures through the lips is discussed. The velocity of the air leaving the flautist's mouth was equal to that of a hurricane, even for low notes.

A New Nemertine

IN 1931, W. J. Dakin and M. G. C. Fordham announced the discovery of a new type of nemertine worm with a multibranched proboscis, *Gorgonorhynchus repens*. Now a complete description of this unusual animal is furnished by the same authors (*Proc. Zool. Soc.*, 1936). It is shown that while it undoubtedly represents a new and remarkable genus, it is a member of the family Lineidæ of the Heteronemertini. When introverted, the proboscis lies in a closed cavity, the rhynchocœlom, on the dorsal side of the alimentary canal. When everted, the proboscis is a hollow dichotomously branched dendriform structure. At the beginning of the eversion, a single stump appears; this divides into two, four and finally a large number of fine branches. The tips of fine ends can be seen during retraction through the transparent walls. It is this much-branched proboscis, without parallel in the nemertines, that is the outstanding feature of the species. In spite of this, however, the general structure of *G. repens* shows clearly its relationship. The first specimens were found on the coast of New South Wales but afterwards from farther north on the same coast, from islands in the Great Barrier Reef, from India, and recently a worm of the same genus, if not indeed conspecific, has been sent to the authors from Bermuda.

Pycnogonids from Puget Sound

The above is the title of a paper by Harriet I. Exline (*Proc. United States Nat. Mus.*, 83, No. 2991; 1936) in which five species are described, three of which are new. All were collected on dredging expeditions of the University of Washington's research ship *Catalyst*. Pycnogonids are not commonly dredged in Puget Sound, but they are sometimes found in large numbers in certain isolated localities. In the waters around the San Juan Islands, which have been quite thoroughly investigated, probably only half a dozen specimens have been collected in the past ten years. On the other hand, with the investigation of the waters south of the San Juan, especially in the vicinity of McNeils Island, pycnogonids have been collected in large numbers among hydroids dredged from rocky bottoms. Two of the new species belong to the genus *Nymphon* and one to *Ammothea*.

Virus Diseases of the Potato

The number of virus diseases which attack the potato, with their permutations and combinations, render the study of this branch of science rather complicated. Viruses are, fortunately, capable of classification into definite groups, and with exchange of material between the workers in Holland, Great Britain and America, the relations of the different virus complexes are gradually being elucidated. A recent paper by Prof. P. A. Murphy and J. B. Loughnane (*Sci. Proc. Roy. Dub. Soc.*, 21, No. 40; Sept. 1936) compares some Dutch and Irish potato mosaic viruses. The diseases from Holland show the presence of the viruses designated X, B, Y, A, F, and vein-bending virus, and they occur either alone or in combinations. Slight variants from the forms A and Y were found, and the viruses X, Y and F did not always produce symptoms upon their hosts. Complex-diseases included veinal mosaic (Y or A), rugose mosaic or leaf-drop ($X + Y$), crinkle ($X + A$), and interveinal mosaic ($X + F$). The paper should make a material contribution to an international understanding of potato virus nomenclature. It should be read in conjunction with the American work upon the same subject (K. Koch and J. Johnson, *Ann. App. Biol.*, 22, 37; 1935). The potato virus known as aucuba mosaic has received detailed study from Dr. Phyllis Clinch, J. B. Loughnane and Prof. P. A. Murphy (*Sci. Proc. Roy. Dub. Soc.*, 21, No. 41; Sept. 1936). The aucuba virus produces a typical yellow mottle upon the leaves, but this type of symptom also appears with two other viruses, namely, the 'tuber-blotch' virus, and a virus latent in the Dutch potato Monocraat. These last two are probably identical, and it is proposed to designate them virus F, whilst virus G shall denote the active principle of aucuba mosaic.

Economic Effects of Sugar Cane Streak Disease

Wherever the effects of a virus disease upon a crop of economic importance have been investigated, some striking figures are brought to light. Messrs. A. P. D. McClean and R. H. Halse have made a large-scale survey of the sugar-cane districts of South Africa, which should leave no one in any doubt about the economic significance of the streak disease (*Proc. S. Afr. Sugar Technologists' Assoc.*, 1936). Approximately 241,220 tons of cane, with a value of £170,864, were lost in 1934–35, as a result of its ravages. Zululand had the heaviest infection, more than ninety per cent, the Natal districts south of Durban had 62 per cent on ratoon cane, and 48 per cent on plant cane. North of Durban, the disease was less severe, with 26 per cent and 19 per cent on ratoon and plant cane, respectively. The paper also makes some constructive investigation of several of the new varieties which have recently found favour in commercial practice. Those designated Co 290 and POJ 2725 are moderately resistant, whilst the POJ varieties 2714, 2722, and 2878, with Co 281, are highly resistant. One is left with the impression that the streak disease may well be controlled in the near future.

Time Discharge of Condensers

Everyone who has experimented with electric condensers knows that some types absorb a certain amount of electricity which does not come back immediately when the condenser is discharged. It is gradually liberated and accumulates on the plates as a residual discharge. This 'oozing out' effect is sometimes explained by assuming that a process analogous to viscous action is taking place, and that this prevents the immediate return to the normal state. The amount of the residual charge and the relaxation rate at which it is freed are of importance to the telephone engineer owing to the large number of condensers used in telephone apparatus. The explanation of the effect usually given starts with the assumption that dielectric absorption is due to an action of the molecular structure which takes place uniformly throughout the material. In a paper on this subject by W. A. Yager in the *Bell Laboratories Record* of November, it is shown that the relaxation effect is much too complicated to be explained in this simple way. The results show that the residual current involves a combination of relaxation times. A successful explanation has been made by K. W. Wagner, who postulates that the number and magnitude of the relaxation times are determined by the laws of chance. For the simple theory we get fair agreement for dielectrics, like pure liquids, of relatively simple constitution. But for dielectrics of even moderate complexity the simple formula is practically worthless. Wagner's equations appear to be applicable to systems of all degrees of complexity and it is concluded that a helpful advance in the theory of dielectric action has been made.

High-Permeability "Furukawa Magnetic Alloy"

In the September issue of the quarterly journal *Nippon Electrical Communication Engineering*, published in English by the Institute of Telegraph and Telephone Engineers of Japan, there is an important article on the new high-permeability magnetic alloy made by the Furukawa Electric Co., Ltd. In low magnetic fields it is known that this new alloy has a much higher permeability than the English mumetal. Its composition is now described, and we are told that its manufacture is protected by Japanese patents. It is manufactured in four grades called A, B, C and D respectively, each being suitable for specific purposes. These alloys are uniform and easy to work at any temperature. They can be rolled into transformer sheets as thin as 0·1 mm. or drawn into very fine wire. The time required for the heat treatment of these alloys is very short, and after taking the metal from the furnace it can be cooled in the air. The *A* alloy is of very high electric resistance, and is specially suited for the magnetic core of high-frequency devices. The characteristics of the *B* and *C* alloys show that they would be very suitable for use with audio-frequency transformers. The alloy *D* has extraordinarily high permeability, and is highly recommended for the iron cores of very sensitive relays and ammeters for use in electric power lines. By using the alloys for the cores of the transformers employed in aeroplanes, their weight has been reduced to one fifth of the ordinary values. A photograph is shown of a transformer core made of stalloy having a weight of 1,010 gm. and of another made of the new magnetic alloy fulfilling the same functions and weighing only 75 gm.

Atomic Weight of Arsenic

IN 1933 Baxter and Shaefer carried out two series of estimations of the atomic weight of arsenic by analysis of the tribromide and obtained the values 74·919 and 74·901 respectively. This led to the acceptance of the value 74·91 for the atomic weight of arsenic. This is 0·02 units below that found by Křepelka in 1930, which was adopted at the time by the International Committee for Atomic Weights. Křepelka and Kočnar have now (*Coll. Czech. Chem. Comm.*, 8, 485 ; 1936) synthesized arsenic tribromide from specially pure bromine and arsenic, and from determinations of the ratios $AsBr_3 : 3Ag$ and $AsBr_3 : 3\,AgBr$ they arrive at the new value 74·923, which thus lies between what were hitherto regarded as the most trustworthy determinations. This new value agrees better with Aston's value derived from the mass spectrum (As = 74·934, or 74·925 according to Babcock and Naudé) than the value found by Baxter and his collaborators. Křepelka and Kočnar have taken every precaution to use highly purified materials throughout their work, and whilst the new value lessens the discrepancy between the earlier values of Křepelka and Baxter respectively, there is still a difference of 0·01 unit. The same journal contains a paper from Prof. Moles of the Madrid Instituto Nacional de Física y Quimica dealing with the atomic weight of iodine and advocating the value I = 126·917.

Locomotive Fuel Economy

INVESTIGATIONS into the problems of combustion in locomotive boilers and prevention of fuel wastage have in the past been hampered by lack of a method for determination of unburnt fuel loss. A suitable technique has, however, now been evolved on the basis of a suggestion put forward by A. C. G. Egerton, and this was described in a paper by Dr. P. Lewis-Dale at a meeting of the Institute of Fuel on November 25. The principle of the technique is to carry out experiments similar to those usually employed for stationary boilers on the locomotive boiler while it is actually in service. This involves analysis of the exhaust gas, measurements of rate of combustion, amount of unburnt carbon and temperature of exhaust gases. In addition, analyses of the coal used, weighing and analysis of the ashpan ashes and various temperature measurements are essential to accurate interpretation of results. The investigation is in every case designed to last throughout a complete journey of the engine, and thus varying conditions of gradient, curves and wind are taken into account. A number of valuable observations have been made as a result of investigations of this description, the most valuable conclusion reached being that under certain working conditions the loss of heat due to unburnt carbon approximates 30 per cent of the heat which would have been generated by complete combustion of all coal fed to the furnace.

Automatic Starting Resistances

ON switching on electrical machines, very large currents may be obtained initially unless suitable starting 'resisters' are used. These resisters are varied by hand, being large resistance at the start when the counter electromotive force due to the rotating armature is zero and being all cut out when the machine is running at full speed. In the *Philips Technical Review* (Eindhoven) of July a description is given of new automatic starting resistances manufactured by the firm. The starting tubes, which have the trade name of 'starto' tubes, have a large negative resistance coefficient, that is, the higher their temperature the less their resistance. In this respect they are similar to the filament of an electric lamp or to a glass rod, which at ordinary temperatures has a very high resistance but when red hot has comparatively a very low one. These tubes work on the exactly opposite principle to the hydrogen-filled iron filament resisters, sometimes used as regulators, the resistance of which increases rapidly with the temperature. In starto tubes the semi-conductor used is a mixture of silicon and a ceramic 'binder'. The silicon itself does not possess a pronounced negative temperature coefficient, but on diluting with a suitable binder it has a large negative resistance coefficient. The resistance material is formed in the shape of a rod which is fixed inside a glass tube filled with argon. This filling is required because the silicon of the rod reacts with oxygen and hydrogen. The tubes are designed for different maximum currents of between one and a hundred amperes. On full load the rod is raised to red heat and its temperature is then about 800° C. Starting tubes can also be used to switch on lamps automatically when it is desired, as in theatres and cinemas, to light them up gradually. These starting tubes can be used for many other applications in electrical working.

The Galaxy

IN the issue of *Scientia* of December, Dr. J. S. Plaskett, of the Astrophysical Laboratory, Victoria, British Columbia, describes the progress made recently in our knowledge of the extent of, and the distribution of stars in, the Galaxy, and sums up the results obtained. In its main features it resembles the Andromeda Nebula—that is, a flat disk nearly circular 30,000 parsecs (each 3¼ light years) in diameter and 1,000–2,000 parsecs in thickness, in rotation about its axis and containing about ninety per cent of the total mass. Within this disk the star density decreases from centre to circumference and rapidly near the edge. Throughout the disk and for 5,000 parsecs beyond its edge and 10,000 parsecs on either side of it are scattered high-velocity stars and clusters, and near its central plane is a light-absorbing medium 500 parsecs in thickness. The sun is situated in the central plane 10,000 parsecs from the centre (in a direction away from Vega ?) and has a velocity of 275 kilometres per second, which would give the period of rotation of the Galaxy as 224 million years.

The Bowl of Integers and the Hexlet[*]

By Prof. Frederick Soddy, F.R.S.

INTO a hollow sphere of unit radius, with a curvature or bend, therefore, -1, put two solid spheres of radius $\frac{1}{2}$, or bend $+2$. The two solid spheres then kiss each other at the exact centre of the bowl, and kiss the latter at the extremities of its diameter through all three centres, no other disposition being theoretically possible. This three-sphere assembly may be termed the 'bowl of integers', since it has the unique property that the bend of every sphere of the infinitely infinite number of spheres that theoretically can be packed into it, so that each is located by its neighbours, is an exact integer which can be written down at once from those of its neighbours. It enables the nature of the 'hexlet' to be elucidated without either trigonometry or the algebra of irrationals.

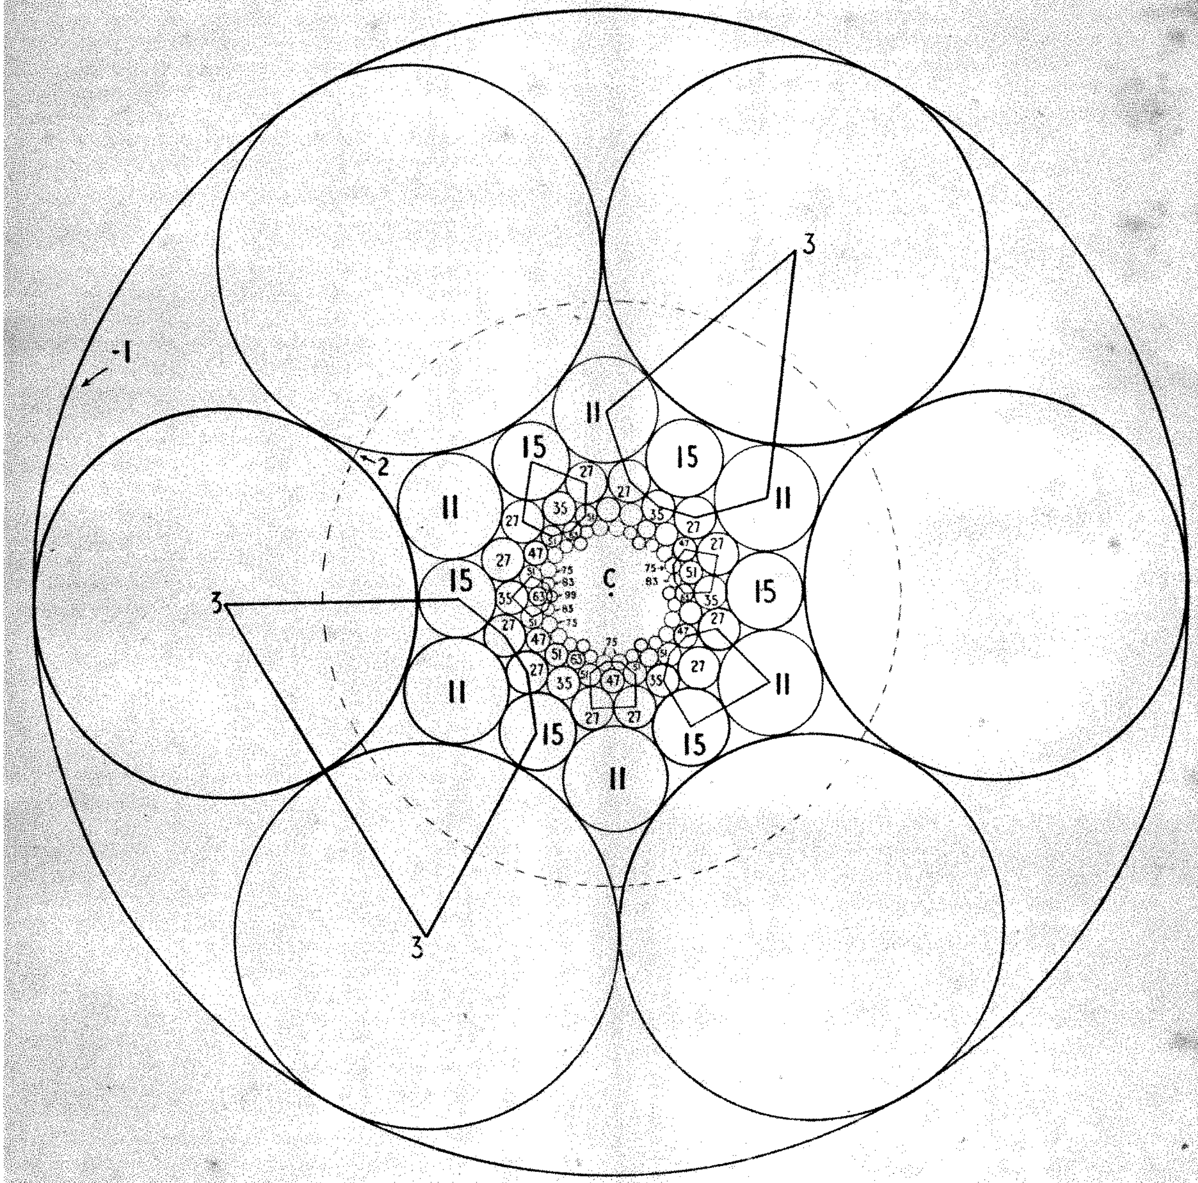

Fig. 1.

Fig. 1 shows a section through the bowl of integers through its centre, *C*, in the plane of the paper, which is also the point of contact of the two 2-spheres, one of which is above and one below it, the centres of the latter and their points of contact with the bowl being on the line through *C* vertical to the plane of the paper. The circle shown by a dotted line is the 2-sphere below the plane of the paper, and the figures labelling the circles are the bends, or reciprocals of the radii, of the spheres centred in the plane of the paper, of which they are sections. The space between the two 2-spheres and the bowl has been packed by successive rings of spheres, each ring in passing inwards consisting of ever larger and larger numbers of smaller and smaller spheres, until as we approach *C* they become infinitely small and infinitely numerous. All are in contact with the two equal 2-spheres above and below the plane of the paper, and all, being centred in this plane, are accurately represented by circles. So we may imagine similar rings of spheres above and below the plane of the paper, each in contact with the bowl and with one of the two 2-spheres, and then begin all over again to fill up the remaining spaces and so on *ad infinitum*, every sphere added increasing the number that have to be added to fill it up!

---

[*] *Vide* "The Kiss Precise" and "The Hexlet" (NATURE, **137**, 1021, June 20, and **138**, 958, December 5, 1936).

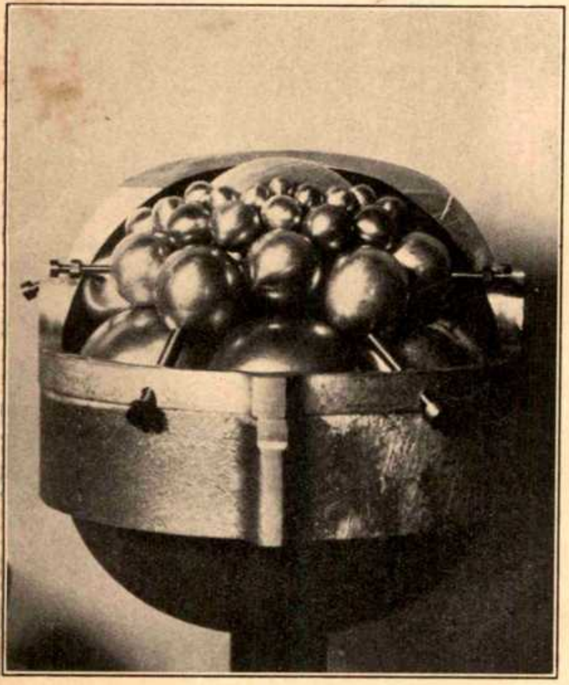

Fig. 2.

These further spheres being spaced in three dimensions cannot be accurately represented by a drawing, but they are all characterized by exactly integral bends. I discovered this years ago for the simpler case of cylinders, or circles, in connexion with the design of an actual mechanism, but it is true also for the spherical analogue. So long as the sum of the two radii of the two largest equals that of the enclosure, the bends are always rational, and when the largest two are equal in radius, integral with respect to that of the enclosure as unit. So far as I am aware, this has not before been observed.

From the case illustrated, the principles of the hexlet are easily exhibited. The largest spheres that can be fitted in after the two of radius 1/2 are a ring of six of radius 1/3, the centres of which are at the corners of a regular hexagon. It is the simplest case of the hexlet; all six spheres being equal, the bend, 3, is simply the sum of those of the common trio, namely, $2 + 2 - 1$. Going inward towards *C* the next ring has twelve spheres, six 11's alternating with six 15's; the next has 18, six contiguous pairs of 27's alternating with six single 35's; the next twenty-four, the series, 63, 51, 47, 51 being six times repeated round the periphery; and the last to be shown in the diagram has thirty, the unit series being 75, 83, 99, 83, 75.

Seven different hexlets belonging to the pair of 2-spheres and, respectively, to the 11, 15, 27, 35, 47, 51 and 63 spheres are indicated by the irregular hexagons formed by the six lines joining the centres of the hexlet. In every case the sum of the bends of any two opposite members is twice that of the central member plus 4, the latter being the sum of the bends of the two 2-spheres common to all the hexlets. Thus to take the last and smallest,

$$99 + 35 = 83 + 51 = 51 + 83 = 2(63 + 2 + 2).$$

In the same way each of the six 3-spheres is the centre of a hexlet, -1, 3, 11, 15, 11, 3, opposite members of which sum to $2(3 + 2 + 2)$. Three being given, the other three may be written down without further calculation. The hexlet round the 27- and 51-spheres are unsymmetrical. The others exhibit three different types of symmetry.

Fig. 2 shows a model of the bowl of integers with the tangential hexlets of the upper half, each sphere being in contact with the bowl and upper of the two 2-spheres. The unit series, six times repeated round the periphery, are for the successive rings I, 3; II, 6, 5; III, 11, 9, 9; IV, 18, 15, 14, 15; V, 27, 23, 21, 21, 23; VI, 38, 33, 30, 29, 30, 33 and so on.

In complete generality, the hexlet derives as follows. As a corollary of Euclid (ii, props. 11 and 12) that the centres and point of contact of kissing circles are collinear, *any* three spheres can make mutual contact, all three centres being necessarily in one plane, forming a triangle any two sides of which are necessarily greater than the third. But a fourth sphere may make mutual contact with them only if its size is between a maximum and minimum limit, which values apply when the centres are co-planar. Its size and position in space relatively to the others are dependent variables. The centre of the fourth, at its maximum say, may move out of the plane containing the centres of the trio, and the fourth sphere may retain contact with the trio anywhere in a closed orbit cutting the plane twice per revolution at the maximum and minimum, but only by shrinking or swelling in size between these two limits. These maximum and minimum values are those for the particular case when the hexlet round the trio is symmetrical (as in the hexlets in Fig. 1 round spheres 15, 35 and 63), and is divided into symmetrical halves by the plane containing the three centres of the trio and the two of the opposite largest and smallest beads. These values are, since for this case the centres are co-planar, the two roots of the quadratic equation for four *circles* in mutual contact ("The Kiss Precise", verse 2):

$$2(\varphi^2 + \alpha^2 + \beta^2 + \gamma^2) = (\varphi + \alpha + \beta + \gamma)^2,$$
$$\text{or } \varphi \pm = \alpha + \beta + \gamma \pm 2\sqrt{\alpha\beta + \alpha\gamma + \beta\gamma} \qquad (1)$$

where φ stands for the bend of the fourth sphere and α, β and γ for those of the trio, the sum of which will be termed σ. Equation (1) may be written $\varphi_{\pm} = \sigma \pm 2\rho$, where ρ is the bend of the circle inscribed in the triangle formed by joining the centres of the trio. $\varphi_{+} + \varphi_{-} = 2\sigma$.

But if the fourth sphere has any other value, say δ, between the maximum and minimum, the centres are no longer co-planar, but four bends being fixed, the fifth is determined by and can be found from the quadratic equation for five spheres in mutual contact (*ibid.*, verse 3).

$$3(\varphi^2 + \alpha^2 + \beta^2 + \gamma^2 + \delta^2) = (\varphi + \alpha + \beta + \gamma + \delta)^2$$
$$\text{or } \varphi \pm = \tfrac{1}{2}[\alpha + \beta + \gamma + \delta \pm \{6(\alpha\beta + \alpha\gamma + \alpha\delta + \beta\gamma + \beta\delta + \gamma\delta) - 3(\alpha^2 + \beta^2 + \gamma^2 + \delta^2)\}^{1/2}] \qquad (2)$$

As always, we get two real roots, which refer, not to opposite beads of the hexlet as in the two-dimensional equation, but to the two on either side of the one to which the bend, δ, has been assigned. Hence we have

$$\varphi_{+} + \varphi_{-} = \sigma + \delta\,; \text{ or } \varphi_{N+1} + \varphi_{N-1} = \sigma + \varphi_N\,; \text{ or } \varphi_3 = \sigma + \varphi_2 - \varphi_1,$$

where φ_{N+1}, φ_N and φ_{N-1} refer to the bends of any three consecutive beads. From this, any two consecutive beads being known, all the others can be written down at once, when it will be found, quite unexpectedly I think, that this simple relation conceals a periodic function, with a period of six, or $\varphi_{N+6} = \varphi_N$. Thus the six beads have values, in terms of those of any two consecutive beads, φ_1 and φ_2, (1) φ_1; (2) φ_2; (3) $\varphi_3 = \sigma + \varphi_2 - \varphi_1$; (4) $\varphi_4 = \sigma + \varphi_3 - \varphi_2 = 2\sigma - \varphi_1$; (5) $\varphi_5 = \sigma + \varphi_4 - \varphi_3 = 2\sigma - \varphi_2$; (6) $\varphi_6 = \sigma + \varphi_5 - \varphi_4 = \sigma + \varphi_1 - \varphi_2$; (7) $\varphi_7 = \sigma + \varphi_6 - \varphi_5 = \varphi_1$.

It will be seen that the sum of the bends of each opposite pair remains constant at 2σ, though *any* value δ between limits was given to the one bend arbitrarily fixed. The hexlet in fact is free to revolve round the trio without loss of serial contact, or separation of its several beads each from contact with all three of the trio. Similarly any given hexlet may be fixed and the trio varied through a definite cycle in which σ remains unchanged but the three individual bends vary interdependently.

The primary hexlet of the bowl of integers *is* free to revolve in its tri-spherically sided annulus without change of grade, because exceptionally all its beads are identical, and this property is not due to two of the spheres of the trio being equal, but derives from the sum of their radii being equal to that of the bowl. Using Roman letters for radii, A and B may have any values so long as they sum to C, or using Greek letters for bends, so long as $1/\alpha + 1/\beta + 1/\gamma = 0$. When we introduce this value for γ into the surd of equation (1) for four circles in mutual contact $\alpha\beta + \alpha\gamma + \beta\gamma$, it vanishes and $\varphi_{+} = \varphi_{-} = \sigma$. When we introduce these values for γ and δ, δ being the φ of equation (1) when $\varphi_{+} = \varphi_{-}$, into equation (2), its surd

$$6(\alpha\beta + \alpha\gamma + \alpha\delta + \beta\gamma + \beta\delta + \gamma\delta) - 3(\alpha^2 + \beta^2 + \gamma^2 + \delta^2), \text{ or } (\varphi_{+} - \varphi_{-})^2,$$

also becomes zero, and $\varphi_{+} = \varphi_{-}$. That involves that all the six spheres of the hexlet are identical, because the opposite members as well as those on each side of them are all equal.

In conclusion, one point of really fascinating historical interest emerges. The Greeks, in their study of the αρβηλος or "shoemaker's knife", obtained by pure geometry the radius of the fourth circle that will make mutual contact with a mutually tangent trio for which $A + B = C$, whatever the ratio $A : B$. The proposition from the Arabic "Liber Assumptorum" will be found in full with notes in Sir Thomas Heath's "Works of Archimedes", p. 307 (Camb. Univ. Press, 1897). In the actual figure by which the proof was demonstrated A/B was 3/2, which gives for the radius in question 6/19, in terms of C as unity, when, therefore, A is 3/5 and B is 2/5. Since $\varphi = \sigma$,

$$\varphi = 5/3 + 5/2 - 1 = 19/6\,!$$

It is curious this should have remained unnoticed for thousands of years. Possibly when a mental arithmetic of reciprocals becomes as natural as that of number we may hope to learn the real secret of the circle and the sphere.

Climatic Discomfort

MR. W. F. TYLER, an engineer interested in meteorology, was led to make an investigation into the connexion between climatic discomfort and the state of the atmosphere in regard to temperature and humidity. A summary of his work is to be found in a reprint of a paper read before Section J (Psychology) of the British Association at Blackpool.

Mr. Tyler began his work at Shanghai more than thirty years ago. He was helped by the late Father Froc, then director of Siccawei Observatory, Shanghai, and by twelve observers—well-educated, intelligent men, one gathers—who during the month of August 1902 made an observation at every noon of their sensation of discomfort from the heat and dampness while sitting quietly in their offices, cooled by the punkah or fan to which they were accustomed. Their sensations were recorded on an arbitrary scale extending from 1 to 10; the numbers on the scale have been called hythers, hyther 10 being taken to represent an "unbearable condition". As the result of these determinations we have a very interesting diagram in which the hythers are shown as sloping, nearly parallel, slightly curved lines derived from plottings of the individual observations with temperatures as abscissæ and the differences between the dry and wet bulb thermometers as ordinates. The course of each hyther shows how much change in the depression of the wet bulb was required on an average to prevent any given change of temperature from altering the discomfort appropriate to that hyther.

One is tempted to criticize this fundamental diagram, on which a number of climatic studies have been based, on the grounds that the data are too meagre, that one individual differs greatly from another in response to atmospheric conditions, and that each varies according to health, state of mind and other influences, but Mr. Tyler surely deserves credit for trying to bring more precision into the psychology of hot climates, and his work should be of practical value in problems of air conditioning in such climates. Hythers suitable for temperate climates might be useful to European weather forecasters in more scientific times in the future, when air temperature and discomfort may be forecast separately. The general public does not know that in present-day forecasts the forecaster's references to temperature apply to temperature recorded in a screen designed to remove the vitally important effects of radiation. This fact results often in the anomaly of the forecaster knowing that he has made a technically correct forecast while even intelligent readers of the forecast imagine that it has gone utterly astray. But the hyther system would be more likely to give useful results in the near future in the comparison of different climates with very large contrasts of temperature and humidity.

The usefulness of a scale of discomfort of the type used by Mr. Tyler is apparent from a recent article entitled "Temperature Profiles in Toronto" by W. E. Knowles Middleton and F. Graham Millar (*J. Roy. Ast. Soc. Canada*, Sept. 1936). It is an account of observations of air temperature made with a nickel resistance thermometer of small lag, well shielded from radiation, which was mounted two feet from the front of a car 27 inches above the road. The observations were made in a street that runs north-north-west from the shore of Lake Ontario to the northern limit of the town of Toronto and continues as a paved highway several miles farther in the same direction. Observations of this kind, it may be noted, were made by H. Tollner in Vienna in 1931 (*Sitz. Akad. Wiss. Wien, Math. Nat. Kl.*, Abt. II$_a$, 141, 1–13; 1932). The results of a few selected sets of observations are discussed. They are shown as graphs with temperature as ordinates and distances from the lake as abscissæ. The elevation of the land is also plotted, so that temperature variations can be related at a glance to the changes of elevation. On a hot sunny day with light southerly wind, a very sharp rise of temperature was observed in the first 200 yards from the lake front and then an average increase of 1·3° F. in each mile for five miles, after which temperature fell a few degrees in the more countrified surroundings. At such times workers in offices near the lake have the advantage in temperature but experience a higher humidity and dew point as compared with their families in the residential parts higher up and farther from the lake. In the absence of a sensitive scale of climatic discomfort on the lines of the scale obtained by Tyler, it is difficult to form an idea as to which of the two is the better off. Another graph for a clear winter night showed a difference of no less than 27° F. between the bottom of a valley and its crest, for a difference of height of about 120 feet.

Chemistry of Essential Oils

IN the nineteenth Streatfeild Memorial Lecture, delivered at the Institute of Chemistry on November 20, Prof. John Read, of the University of St. Andrews, described a chapter in organic chemistry of extraordinary fascination. He showed how the discovery by Captain Cook of Australia opened a new field of research in the related sciences of botany and chemistry, which was soon appreciated by the early settlers in that continent.

Dr. John White, Surgeon-General to the first settlement at Botany Bay under Governor Phillip, and First Assistant Surgeon D. Considen, both referred in or about 1788 to a large peppermint tree growing around Port Jackson, the essential oil of which bore a close resemblance to that obtained from peppermint (*Mentha piperita*) long grown in England. This Australian tree, now known as *Eucalyptus piperita* or the Sydney peppermint, was supposed to contain the same odoriferous constituent, menthone, as the English tree. But in 1900 this peppermint odour of the genus *Eucalyptus* was shown by H. G. Smith to be a distinct ketone to which he gave the appropriate name of piperitone.

Prof. Read compared Smith with Streatfeild as regards his Kentish origin and his unselfish devotion to practical organic chemistry. Migrating to Sydney for reasons of health, Smith took up the study of chemistry and devoted himself especially to the chemistry of the Australian flora. His most remarkable work on the chemical nature of the essential oils of the genus *Eucalyptus*, which includes three hundred species, has an important bearing on the development of the natural resources of Australia. Certain oils were found to be rich in cineole, phellandrene, geraniol, citral, pinene and piperitone, whereas others yielded new chemical constituents peculiar to the Australian flora. Some of these researches were carried out in collaboration with Profs. Read and J. C. Earl, both of whom were former pupils of Streatfeild.

Piperitone, which is a key to the stereochemistry of the menthones, menthols and related substances, is invariably lævorotatory when obtained from eucalyptus, whereas from a Himalayan grass *Andropogon Jwarancusa* it was isolated by Simonsen in the dextrorotatory variety (1921).

Prof. Read then showed how the systematic study of the piperitones as pursued at St. Andrews has disclosed a new approach to the menthols and their congeners. These stereochemical researches offer a clue to the biogenetic relationships of the constituents of essential oils, some of which were traced by Smith and his co-workers. According to Baker and Smith, the open chain, geranyl acetate, passed into *Eucalyptus* through *Angophora* (an Australian genus of Myrtaceæ) and probably runs through the whole of the eucalypts although sometimes present only in small amounts.

In most species of eucalypts, geraniol may be presumed to function as the precursor of *l*-piperitol, *l*-piperitone, α-phellandrene and allied substances. The delicate control of molecular mechanism takes, however, a different turn in the Indian grasses, where geraniol becomes transformed into the enantiomeric *d*-piperitol, *d*-piperitone and into Δ^4-carene. In the present stage of knowledge these subtle differentiations are beyond the powers of the chemical laboratory and appear to be inseparably bound up with vital processes. The systematic study of these biochemical phenomena is of wide scientific interest and also of considerable industrial significance. G. T. M.

Science News a Century Ago

A Visit to Mount Athos

AMONG the contributions read to the Royal Geographical Society on January 9, 1837, was "An Account of an Ascent of Mount Athos and a Visit to Mountains, in June 1836" by Lieut. Webber Smith, of the 48th Regiment. On the south-east shore of the district of Saloniki, he said, three remarkable peninsulas, twenty-five miles in length by about five miles breadth, project nearly parallel to each other, in a south-easterly direction into the Archipelago. The easternmost of these three promontories, Mount Athos, is joined to the mainland by a low sandy isthmus, about 5 miles long and nearly 1¼ broad; and through which the famous canal was cut by Xerxes. The height of the central plateau of the peninsula is 250–500 feet, and from this rises a giant peak of white limestone about 6,350 feet high. The peninsula contains twenty monasteries, the whole containing about 1,500 men including 300 mendicants. At the village of Kares, a weekly fair or market is held, which presents the uncommon scene of a fair without noise, and a crowd without women; no female is on any account admitted within the precincts of the mount, nor indeed anything it is said of the feminine gender.

Darwin's Gifts to the Zoological Society

ON January 10, 1837, at a meeting of the Zoological Society, "Mr. Reid described several Mammalia, which were on the table, forming part of an extensive collection in Natural History, presented to the Society by Mr. Darwin, who accompanied the surveying ship *Beagle*, in the capacity of naturalist to the expedition. The whole contains upwards of 80 varieties, whilst the birds consist of nearly 450 specimens, including about 150 species, eleven of which from the Gallapagos Islands, were described by Mr. Gould, as being of entirely new forms to this country" (*Athenæum*).

An Epidemic of Influenza

UNDER the date January 12, the *Annual Register* for 1837 said that an influenza of a peculiar character had been raging throughout the country, and particularly in the metropolis. It was attended by inflammation of the throat and lungs, with violent spasms, sickness and headache. So general was its effects, that business in numerous instances was entirely suspended. The greater number of clerks at the War Office, Admiralty, Navy Pay Office, Stamp Office, Treasury, Post Office and other Government offices were prevented from attending to their daily avocations. Of the police force, there were upwards of 800 incapable of doing duty.

Death of Rev. William Farish

ON January 12, 1837, the Rev. William Farish died at Little Stonham, Suffolk, at the age of seventy-eight years. Born in 1759, he was the son of a clergyman of Carlisle, and after attending Carlisle Grammar School entered Magdalene College, Cambridge, as a sizar. He graduated in 1778, and was senior wrangler and Smith's prizeman. In 1794 he was appointed professor of chemistry at Cambridge, and as such he made a point of showing the application of chemical science to the arts and manufactures. In 1813 he was appointed to the Jacksonian professorship of natural philosophy, being the successor of Francis John Hyde Wollaston (1762–1823) and the predecessor of Robert Willis (1800–75). In 1800, Farish became the incumbent of St. Giles's, Cambridge, and in 1836, rector of Little Stonham.

Dr. Roux on the Removal of Cataract

IN a note in the *Athenæum* of January 14, 1837, it is stated, "In making a report before the French Academy of Sciences, concerning the work of M. Maunoir, in favour of extraction of cataract from the eyes, M. Roux adduces the result of his own practice. Having registered all his operations during ten years, for the purpose of ascertaining which was the most efficacious method, he has been induced to give the preference to extraction. During this period he performed more than six hundred operations, as much as possible under similar circumstances, and the advantage gained by extraction was one-sixth".

Joseph Philibert Roux was born on April 26, 1780, and died on March 24, 1854, shortly after publishing "Quarante années de Pratique chirurgicale".

The British Medical Association

THE *Lancet* of January 14, 1837, contains the following notice. "The first public meeting of the members of the British Medical Association will be held at Exeter Hall in the Strand at six o'clock for seven precisely on Thursday evening next, the 19th inst. . . . This is essentially a NATIONAL association; it is open to the reception of all classes of medical practitioners; but it has been most prudently determined that the President shall always be a surgeon who is engaged in *general practice*, and that all the Councillors shall have been or shall be general practitioners. The thousands of our professional brethren have now only to unite in a spirit of cordial co-operation, under a governing body, thus qualified, constituted and interested in upholding their rights and within a very brief period the immense majority of surgeons in this country will find that they are enabled to take their proper station in Society. . . ."

Instances of Early Maturity

IN a lecture on forensic medicine delivered at the Aldersgate-School of Medicine and published in the *London Medical Gazette* of January 14, 1837, Dr. William Cummin remarked that though it was only the infant produced at the ninth month of intra-uterine life that could be considered completely mature, there were numerous instances of children born at earlier periods sufficiently mature to run the normal course of human existence. Numerous old writers such as Avicenna, Schenck, Spigelius, Valesneri, Ammianus and Diemerbroeck among others had recorded examples of children having lived to adult age and even to the ordinary limits of human life though born after only five months of conception. Fortunio Luceti, according to Capuron, though born at the age of five months, lived to the age of seventy years. When born he was no bigger than a man's head. Belloc recorded the case of a female infant born about the sixth month who was only a foot long and looked like a little skinned rabbit, yet she was carefully fed and lived to woman's estate. Marshal Richelieu was recognized as viable by the parliament of Paris, although born only at five months.

A. Erdélyi : Development of an analytical function in terms of Whittaker functions.

J. Gillis and J. Eeckhout : Quantitative investigation of the ion exchange produced by the addition of the nitrates of thorium, hexol and cerium to the negative sol of silver iodide.

H. G. Bungenberg de Jong and L. Teunissen-van Zijp : Further examples of unmixing in aqueous salt solutions.

L. Algera : Influence of temperature treatment on the carbohydrate metabolism, the respiration and the morphological development of the tulip (3).

J. Kuyper and L. K. Wiersum : Occurrence and transport of a substance causing flowering in the soya bean (Glycine Max L.).

J. Westerveld : Geology of North Banka, Djeboes (Dutch East Indies).

A. A. Thiadens : Some caprinids and a monopleurid from southern Santa Clara, Cuba.

J. L. Addens and T. Kurotsu : The pyramidal tracts of *Echidna*.

F. J. Nieuwenhuyzen : Chronic experimental catatonia produced by intermediate products of metabolism. Indolethylamine.

Cape Town

Royal Society of South Africa, September 16.

R. F. Lawrence : The external sexual characters of South African harvest spiders.

G. P. Lestrade : Notes on the political organization of certain Xhosa-speaking tribes in the Transkeian Territories The political organization of the Gcaleka, Mfengu and Thembu tribes in the Transkeian districts of Willowvale, Idutywa and Engcobo is described. An account is given of the territorial organization obtaining among these tribes ; and the various political units into which they are divided—the kraal, the ward, the tribal division, and the tribe—are described.

R. S. Adamson : Anomalous secondary thickening in *Ostrospermum*.

Moscow

Academy of Sciences (*C.R.*, 3, No. 9 ; 1936).

M. M. Greenblum : Geometrical structure of the symmetric transformation in Hilbertian space.

P. I. Lukirsky and T. Careva : Slowing-down of neutrons by the nuclei of heavy elements.

D. A. Čerenkov : Influence of a magnetic field on the visible luminosity of fluids produced by gamma-rays.

P. D. Lazarev, E. M. Klinkovstein, Z. V. Bulanova and S. S. Katznelson : Study of the visual adaptation in the normal and pathological state of the organism. (1) The influence of diabetes mellitus on adaptation in peripheral vision.

N. A. Slioskin : The problem of motion of a gas in two dimensions.

M. Michailov and J. A. Arbuzov : Thermal decomposition of olefinic hydrocarbons.

V. S. Butkevic : The formation of oxalic and citric acids by fungi.

R. A. Rubin : The biose/monose ratio as a biochemical varietal character in the onion.

A. Nikiforova : Boundary between the Permian and the Carboniferous in the reef limestones of the Urals established on the basis of the Bryozoa enclosed therein.

N. G. Cholodnyj : Hormonization of grains.

M. C. Čailachjan : The hormonal theory of plant development.

L. M. Šulpin : The faunal features of the north-west Tian Shan.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, January 11

Victoria Institute, at 4.30.—Sir Ambrose Fleming, F.R.S.: "On the Methods of Determining the Age of the Earth" (Presidential Address).

Royal Geographical Society, at 8.30.—E. T. D. Lambert: "From the Brahmaputra to the Chindwin".

Tuesday, January 12

Society for the Study of Inebriety and Drug Addiction, at 4.—Dr. H. M. Vernon: "Alcohol and Motor Accidents".

Warburg Institute, at 5.30.—Dr. Konrad Lorenz: "Biological Aspects of Play".*

Pharmaceutical Society, at 8.30.—Dr. F. B. Parsons: "Anæsthetic Agents".

Wednesday, January 13

Royal Society of Arts, at 8.—Olaf F. Bloch: "Applications of Photography to Scientific and Technical Problems".

Thursday, January 14

Royal Asiatic Society, at 4.30.—Prof. W. Perceval Yetts: "Chinese Bronze Mirrors".

Appointments Vacant

Assistant (Grade I, Engineering or Physics), ref. 305 E., and **Assistant (Grade III, Engineering)**, ref. 307 E., in the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (January 15).

Assistant Chemist in Somerset County Laboratory—The County Analyst, County Hall, Taunton (January 15).

Established Civil Engineering Assistants in the Headquarters and Divisional Road Engineers' Offices of the Roads Department of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, London, S.W.1 (January 15).

Inspector of **Live Stock** in the Department of Agriculture for Scotland—The Secretary (Establishment Branch), York Buildings, Queen Street, Edinburgh 2 (January 16).

Technical Officer (Mathematics or Physics) in the Meteorological Office—The Secretary (S.2.E.), Air Ministry, Adastral House, Kingsway, W.C.2 (January 18).

Organizer of **Agricultural Education** to the Lindsey County Council Education Committee—The Director of Education, County Offices, Lincoln (January 23).

Lecturer in Organic Chemistry in University College, Exeter—The Registrar (February 1).

Chemist in the A.I.D. Test House, Kidbrooke—The Secretary, Air Ministry, S.2.d., Adastral House, Kingsway, W.C.2.

Horticultural Adviser to the Land Settlement Association, Broadway Buildings, Broadway, Westminster, S.W.1.

Human Problems of Progressive Industry

IN discussing the impact of science upon society in his presidential address at Blackpool to the British Association, Sir Josiah Stamp referred to the necessity of more science to cure the evils which resulted from the impact of science. Ordered knowledge and principles are wanted at every point, and particularly the type of work carried out by the National Institute of Industrial Psychology. Some of its inquiries attempt to improve existing conditions of work. Other investigations endeavour to determine the conditions which allow greater output and efficiency, but much of the work of the Institute is directly designed to combat the evils arising from the new conditions created by modern demands—speed, accuracy and intensity.

While the work of the National Institute of Industrial Psychology thus invokes the aid of many branches of science and is designed to assist in the adjustment of society to the changes caused by technical development, its support is left to personal advocacy. The financial resources of the Institute are only a fraction of the expenditure on research in a single industry, such as rayon, although the contribution of its work to human welfare is immeasurably greater. This absence of assured support to which Sir Josiah Stamp referred so pointedly greatly handicaps the Institute in the prosecution of many of its fundamental investigations. Even if particular industrial firms make use of the Institute's investigators to an increasing extent, industry and society as a whole cannot in this way reap anything like the potential assistance which the Institute could give in smoothing over the transition and readjustment of society under the impact of science.

The endowment of the National Institute of Industrial Psychology, to enable it to carry out its investigations on a scale commensurate with its potentialities in the field of social and industrial welfare, should prove a profitable investment from the point of view of industrial as well as social efficiency, and might well form one of the first objectives of scientific workers in the field of social science. Moreover, the potentialities of vocational guidance, in which field the Institute has carried out such admirable work, as a factor in avoiding misfits and checking juvenile unemployment, can scarcely be said as yet to have received anything like adequate appreciation, although the impending shortage of juvenile labour makes the work the more important.

The importance of research of this type was stressed by Sir Kenneth Lee in an address to the Bradford Textile Society on November 17. Sir Kenneth urged that research on the human side is just as important in modern industry as research on the chemical and physical properties of the products being manufactured. Discontent and unrest are often due largely to working conditions, and a central co-operative research association should give its attention to the investigation of problems of this type. Causes of workers leaving, abnormal labour turnover, absenteeism, or high sickness incidence demand as rigorous attention and investigation as a fall in the efficiency of a manufacturing process, and fatigue and incentives are fields which should amply repay any research carried out in them.

Like so many other speakers on this question, Sir Kenneth Lee once more emphasized the significance of management in industrial efficiency.

The very rapidity of change and development in industry to-day tends to make plant and machinery of secondary importance. The greatest asset of a business is increasingly the ability of its staff. Significantly enough, this is essentially the first point emphasized in the report of an inquiry into vocational education after general education up to sixteen years of age carried out by a Committee on Commercial and Industrial Education of the British Association.

This Committee in its report emphasizes the growing tendency of firms to recruit university graduates, not for their technical knowledge but because of their disciplined mind and trained intelligence, for some of the higher administrative posts in business. Thus increasing use of the university graduate in technical capacities is likely to be paralleled in his employment in administrative capacities. Similarly the Committee notes the tendency of the larger firms to select an increasing proportion of boys from secondary and public schools at the age of eighteen years.

These factors alone indicate the way in which the standard of recruitment is being raised in industry. They also intensify the problem of vocational guidance, the use of which to prevent misfits either at the start or in selection for promotion to higher managerial posts becomes increasingly desirable and important. One of the arguments in favour of part-time education is, in fact, that entrance to employment at sixteen years of age results in fewer ultimate misfits than entry at eighteen years, when valuable time may have been spent in preparing for a particular occupation.

That more strenuous efforts should be made to eliminate or rather prevent misfits occurring in all ranks of industry is undoubtedly true, if we are to attain the standard of efficiency visualized both by Sir Josiah Stamp and Sir Kenneth Lee, and part-time education may be an important factor in that effort. The report makes it clear that the part-time education required to-day is not of the evening-class type upon which such reliance was formerly put and upon which severe comments have been made in recent years. It is part-time day education in which industry has arranged for the release of its young employees during working hours. Moreover, it is suggested that the sandwich type of vocational education, under which alternate periods of, for example, six months, are spent in the works and at school, should be adopted more frequently as a means of training suitable candidates for posts of higher responsibility.

This suggestion is, of course, essentially similar to the seconding of selected individuals of proved ability and sufficient experience for special training in management and administration with the view of recruiting them for the higher managerial posts as vacancies and opportunities occur. The recently announced staff college to be established near Derby by the London, Midland and Scottish Railway is essentially a development on these lines.

Such developments tend to diminish the importance of, and demand for, full-time vocational training for recruits for industry up to sixteen years of age, although at the same time the need for vocational guidance is enhanced and also the efficiency of vocational training after that age. The later age of entry to industry, whether from school or university, will increasingly be accompanied by a short intensive course of training after entering industry, designed to assist in the transition from school to work and in the application of the disciplined mind and scientific principles acquired in a liberal education to the particular problems characteristic of the branch of industry involved.

One important effect of the rising standard of management should undoubtedly be increasingly felt. The management of to-morrow will, as Sir Kenneth Lee suggests, attach increasing importance to the human factor. It will accordingly make much fuller use of methods of vocational selection and guidance, and may be expected to support much more generously and widely investigations on the long-range and practical problems involved, whether the research is initiated within a particular firm or by a research association or by such an organization as the National Institute of Industrial Psychology. Management of this type will not tolerate the position so strongly criticized by Sir Josiah Stamp, but it should not be necessary to wait for the rising standard of administration in industry to secure any important modification of the present anomalous position.

At the present time, apart from the National Institute of Industrial Psychology and the work of the Industrial Health Research Board, little attack is being made on the broader and more general problems akin to the long-range and fundamental work in the physical sciences which is at present so largely the domain of the universities. Even if the work done in the field of industrial relations in different universities were extended to cover the study of social change and of new leys proceeds depends partly on how well the seeds mixture has been designed to suit the system and standard of farming for which it is intended, and how well that standard is maintained.

The *unenclosed grazings* are divided into seven types which include the 'maritime association' in addition to fescue-*Agrostis*, mountain fescue, *Mollinia-Nardus*, cotton-grass moor, heather moor and heather 'fell'; of these, *Mollinia-Nardus* is most widespread (17 per cent of total agricultural land), and is next in area after the cultivated *Agrostis* land.

An important feature of some of this land is the occurrence of mature or immature peat, the latter often referred to as 'mat'. This mat is one of the greatest drawbacks to land improvement. It proved probably the worst impediment to rapid cultivation of grassland ploughed out during the Great War for corn production. These 'mats' are common not only on hill pastures, but also on lowland pastures with acid soils. They are often worst where this acidity is emphasized by the acid-polluted atmosphere of industrial districts. Liming is a cure, but an expensive one in hill areas. On Cahn Hill Professor Stapledon has done valuable work in dealing with these 'mats' mechanically. To get them out of the way so that seed and manures can be brought into immediate contact with the soil is essential to complete success. Comparatively light implements or the plough will deal with very immature 'mats', but the thick tough 'mats' found in the worst cases need some kind of heavy rotary tiller, followed by complete destruction of the 'mat' by burning.

The improvement of these unenclosed types of land has been tried with success at Cahn Hill, where there is a series of experiments that will be of enormous interest for some years. They are not merely trials of methods but also severe tests of the value of those pedigree strains of grasses painstakingly produced by the Aberystwyth workers over a large number of years.

These grassy moors with their mixed associations occupy a very low place in the scale of productivity. Here again Wales has no monopoly; in the Cheviots they are thinly populated by sheep which in spite of low stocking often suffer severe losses from disease. How far this disease is due to parasites or under-nutrition or both is a point under investigation on the Cheviots at the present time. In spite of careful herding, the area closely grazed by the sheep is small. Where it is grazed and trodden there is usually an association of finer grasses occupying perhaps scarcely 10 per cent of the whole grazings, and maybe giving conditions conducive to that parasitic infestation so frequent in these hill sheep. Under-nutrition, especially so far as minerals are concerned, is undoubtedly a factor of importance on these hills, and herbage with extraordinarily low calcium and phosphoric acid has been collected in the Cheviots. Prof. Stapledon's call for more lime, more phosphate, is more than justified, but what is the economical way of supplying it, direct or through the grass? The second alternative is very costly on areas so inaccessible, and, so far as some results go, it is questionable whether basic slag will serve the dual purpose of increasing adequately both calcium and phosphate in the herbage.

But of all these low-grade grazings in their unimproved condition, perhaps a well-tended heather moor is the most valuable possession. Only proper attention, mainly periodical burning, will keep down the inevitable encroachment of *Nardus* or—as William Davies prefers to regard heather as the trespasser—will encourage the heather to take complete possession of fresh areas. Speaking generally, good heather moors are worth attention from the sheep as well as the game point of view. Heather has an extraordinary ability to take up lime even from soils of low base status. The younger shoots of heather may have a calcium content as high as good pasture grass, although the phosphate content is low. Other plants like cotton-grass (*Eriphorum vaginatum*) often associated with the heather are rich in phosplate and poor in calcium. Moreover, the heather has little seasonal variation in composition.

The most striking figure in the tables is the proportion of *Agrostis* pasture (38 per cent) and that on cultivated land. It suggests immediately land once reclaimed and now partially derelict. It represents probably the most promising of the unimproved land—promising, that is, from the economic point of view.

By means of specimen maps of zones of the various grassland types, tables of typical pasture analyses with explanatory notes facing them and the description of procedure in the field, the directions to the ecologist who would deal similarly with some other part of the country are clear; and because of these tables and the maps, not forgetting the main map, the book should prove a most useful book of reference.

If Prof. Stapledon's method of approaching this national problem by simply grading up pastures of one class to the next better class were appreciated and understood, the problem of the better utilization of our land would appear much less fearsome. Soil fertility is most securely locked up in good, well-tended grassland, and it can be drawn upon very quickly. More live-stock, especially cattle, are needed to increase and maintain this fertility and they are also needed to apply those extra fresh foods, meat and milk, demanded by research workers in human nutrition.

J. A. H.

Bio-Climatology

The Patient and the Weather
By Dr. William F. Petersen, with the assistance of Margaret E. Milliken. Vol. 1, Part 1: The Footprint of Asclepius. Pp. xx+127. 3.75 dollars. Vol. 1. Part 2: Autonomic Integration. Pp. xxxi+781. 9 dollars. Vol. 2. Autonomic Dysintegration. Pp. xx+530. 6.50 dollars. Vol. 3. Mental and Nervous Diseases. Pp. xvi+375. 5 dollars. (Ann Arbor, Mich.: Edward Brothers, Inc., 1934–1936.)

IN these volumes Dr. W. F. Petersen, of the Department of Pathology and Bacteriology of the University of Illinois, discusses and illustrates the age-old doctrine of the influence of the weather upon health.

The picturesque thesis which runs through this work, that man is a "cosmic resonator", is only a modern expression of man's relation to Nature as taught by Hippocrates. It belongs to all countries and times, in one shape or another, and sometimes in strange forms, as in astrology. It is usually more conspicuous in popular than in academic medicine. In our own time it has had many powerful exponents—meteorologists and physicians—and has already acquired a sound basis through the work of Loewy, Dorno, de Rudder, Leonard Hill, Hāberlin, Kestner and others in the new science of bio-climatology. There is much to say for the author's criticism that the schools of medicine, with their thought centred on infection, have failed to recognize the cardinal importance of atmospheric environment and inherited constitution. Haldane pointed out that many germs of disease, like the tubercle bacillus, are harmless to the average person, and attack others for unknown reasons. Why? It is time that medical thought turned from the micro-organism to the patient. Man has been described as a nucleus of mentality in a material environment. Certainly the fact cannot be ignored that a long range of physical impressions is continually falling on a corresponding keyboard of receptor organs.

A president of the Royal College of Physicians once remarked to the reviewer that he was unable to believe in the alleged effects of a 'change of air' because chemical analysis had shown that the composition of the atmosphere was everywhere the same. There is, however, abundant evidence to the contrary in the behaviour of plants. Many an 'air taster', highly sensitized no doubt, declares that he feels the influence of the air in one direction or another (stimulant or relaxing) even when halted for a few minutes on a railway platform. There is also the common experience of the cessation of catarrh, and increased appetite and energy, on arrival at a coast that 'agrees with you'. Such reactions occur in normal persons. How much greater sensitiveness may be expected in illness? Hāberlin and his school have demonstrated and measured a series of reactions occurring in delicate children from atmospheric causes. Dr. Petersen holds that in different constitutional states the normal biological reactions are accentuated or modified. The operating mechanism is the autonomic nervous system, which, especially in sensitive subjects, is liable to lose its normal balance and pass into imbalance or dysfunction, and eventually permanent disease. The normal reactions occur in two successive phases, indicated as *ARS* and *COD*. In the former *A* stands for *a*nabolic and (in general) alkalinity, *R* for preponderating *r*eduction and *S* for *s*pasm—the systolic blood pressure rising, with a supposed preponderance of adrenal influence. The tissues are increasingly anoxæmic, with accumulation of carbon dioxide. The *ARS* phase gradually or abruptly gives place to its opposite *COD*—in which *C* stands for catabolism and relative acidosis, *O* for *o*xidation and *D* for *d*ilatation, with falling diastolic blood pressure and supposed thyroid preponderance, the reaction changing to alkaline and carbon dioxide diminishing. These phases may be general throughout the body, more commonly perhaps regional. In a state of health (autonomic balance) the rhythm is normal, but in autonomic dysfunction the peaks and troughs are exaggerated. It is the aim of the present work to relate these abnormal reactions to external physical causes over a wide field of disease.

The degree of temperature and its variability are naturally the cardinal factors in atmospheric environment. Cold regions make large demands on metabolism, increase body heat and a tendency to acidosis. Hot regions evoke minimum metabolism and a tendency to alkalosis. But, unexpectedly perhaps, the tropical climate predisposes to chill, for when occasionally the temperature falls, chill may result because the power of accommodation, so little called upon, is found to be wanting. American experts in heating have shown that temperature by itself is no measure of physiological reaction. What has been called 'effective temperature' in defining 'comfort zones' is an "arbitrary index of the degree of warmth or cold felt in response to temperature, humidity and air movement". Composite impressions of this kind are characteristic of climate, and are especially worthy of study, especially on the path of anticyclones, to a description of which much space is devoted. The author agrees with Huntington in his "Civilisation and Climate" that frequent storms, with decided changes from day to day, are the most favourable to health and mental activity, and that the effective temperature is largely conditioned by latitude, winds and expanses of water. The statement that climate and weather are the most important of environmental factors will now be largely accepted: also that, being too familiar and unimpressive, they are unfortunately generally overlooked by the physician. To speak, however, of atmospheric influences as always stimulating is at least misleading. In England especially, it is now held that sedative effects are equally obvious and important, especially in climatic treatment; and it is certain that these external influences, whether accelerating or retarding, ought not to be disregarded, for they are powerful enough to affect not only the organic but also the psychic functions, and even the social and economic conditions of those who are habitually exposed to them.

The greater part of these volumes is occupied with minute investigation of the reactions of many groups of individuals, exposed to the atmospheric changes exhibited in meteorographs. As bearing on these data, the well-known fact is quoted that sub-minimal stimuli, producing no obvious effect, increase the lability of the cell and when repeated may produce important summation effects. The importance of more precise study of the reactions induced by atmospheric environment is properly emphasized. Many disorders connected with autonomic instability are increasing in the United States. A rational therapeutic principle must be not merely palliative but also must take account of the profound influence of physical influences and dietetics, and their great possibilities in the control of disease.

The author modestly states that these three volumes, extending to 1,800 pages, are only a "puny entering wedge". The reviewer may be forgiven a sigh of relief that every treatise is not framed on such generous lines.

Study of Fungi

A Text-Book of Mycology
By Prof E. A. Bessey. Pp. xv+495. (Philadelphia: P. Blakiston's Son and Co., Inc., 1935.) 4 dollars.

A TEXT-BOOK of mycology that will satisfy all demands is perhaps impossible of attainment by one writer and in a reasonably small volume, so wide is the field now covered by the subject. Prof. Bessey has attempted to meet the need for guidance through the vast amount of work on structure, life-histories and classification of the fungi, and in many respects the result is admirable.

The book opens in the usual way with a general account of the fungi, and this is followed by a brief history of work on the classification of the group. Chapter ii deals with the non-filamentous fungi, and also the Mycetozoa and allied groups, these being included not because the author agrees that they are fungi but because they are still so regarded by many workers, and usually come to the mycologist for identification. Chapters iii—v deal with the Phycomycetes, and Chapters vi—xiii with the higher fungi, three being devoted to Ascomycetes, one to rusts and smuts (as a special class Teliosporeæ), and three to the Basidiomycetes proper. Chapter xiv is concerned with the Fungi Imperfecti. While the space devoted to the latter is a little more than that given in most botanical text-books, the treatment is not as satisfying as is that of other groups. In this case Prof. Bessey has relied for his information on an unpublished thesis by a student of Yale University, H. B. Bender. It is unlikely, on the face of it, that such a work can be anything more than a very uncritical compilation, since even an experienced mycologist would be daunted by the task of revising the whole of this huge assemblage of forms, many of them little known and imperfectly described.

The space given to Phycomycetes may seem disproportionate to the size of the group, but is accounted for by the great interest of these fungi from the points of view of cytology, biology and phylogeny. The author throughout has endeavoured to indicate possible phylogenetic relationships. One may not always agree with his views, but the method of treatment is essential if the student is to attain a grasp of the ultimate ideals of morphology and taxonomy. It is fair to point out that the author indicates alternative views, and in general stimulates the student to think for himself.

In a book of this type, errors and omissions are inevitable, and no doubt any specialist might find small points at which to cavil. To the present writer it occurs that there is no mention of *Sporobolomyces*, the yeast which has called forth so much controversy as to its systematic position. Again, on p. 338 the author assumes that all segregates from the genus *Fomes*, as treated in Saccardo's "Sylloge", produce successive layers of pores, which is certainly not the case either in *Amauroderma* or in most species of *Ganoderma*. Typographical errors are very few; *Dœdalia* and *Cantherellus* (both on p. 351) may be pointed out as unfortunate. The figures are the least satisfactory part of the work in that they are in many cases very poor and coarse reproductions. A comparison of Figs. 17 (p. 46) or 22 (p. 62) with the originals from which they are taken is sufficient to indicate the character of the work in this respect. It is to be hoped that these faults may be remedied in a future edition.

The book is to be recommended for the very full references to literature. At the end of each chapter is a list of relevant books and papers, and Chapter xv is given up to a "guide to the literature for the identification of fungi", the titles being classified into those covering the whole field and those dealing with special groups. It is not and does not claim to be complete, but is undoubtedly a valuable guide to those who may have little idea (and what beginner has?) where to look for information as to the fungi in which they are interested.

Refining of Petroleum

Petroleum Refinery Engineering
By Prof. W. L. Nelson. (Chemical Engineering Series.) Pp. viii+647. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 36*s*.

IT has been frequently urged that the refining of petroleum constitutes one of the most important branches of chemical engineering, and that Great Britain will be at a serious disadvantage so long as this industry is largely non-existent here. Ample evidence for such a claim is afforded by the contents of Prof. Nelson's compilation. He points out that the industry utilizes most of the unit operations of chemical engineering and that the great progress which oil refining is now making technically is due to the adoption of chemical engineering principles.

Petroleum refining in its many branches is a typical chemical process industry conceived on the largest operating scale; it is giving employment to more chemical engineering graduates than any other branch of the chemical industry and it affords likewise the largest single market for chemicals.

The first real refinery was built at Titusville, Pennsylvania, at a cost of £3,000 in 1860, and before many years several hundreds of small refineries were in operation, using the batch system. They were replaced by continuous plants, in which the principle was recognized of allowing the oil to flow continuously in a thin stream over the heating surface. The large modern distillation plants are built up of interconnected units with common heat-exchange systems. The next discovery was cracking both in the liquid and vapour phase, which materially adds to the amount of motor spirit produced from the crude oil. The quantity was still further increased by stripping natural gas and again by the application of the hydrogenation process. The development of distillation in vacuum and of solvent extraction has enabled superior lubricating oils to be produced.

It is perhaps of interest to follow the changes in the public demand for oil products. From 1860 until 1885, the demand was for kerosene or burning oil, and too much low flash-point spirit was looked upon as a disadvantage. In 1885–90 the mineral lubricating oils gradually displaced vegetable oils for all purposes. The advent of the motor-car made petrol the most useful product of the refinery, and after 1914 there was an urge to recover more of it from the crude. From 1920 onwards, fuel oil as a means of producing heat and power came into demand. During the last ten years the methods of producing lubricating oils have been radically changed, and quite recently much more stringent specifications have been imposed for these, adding greatly to their utility. The demand for anti-knock petrol led to further plant developments which, in their wider application, have resulted in improved road oil and asphalt products. The capacity of the oil refineries in the United States is at least four million barrels per day.

Prof. Nelson's book sets out what the refinery engineer may be expected to know. Naturally the fundamental data include a knowledge of the raw material and of the refinery products, including the evaluation of oil stocks. The principles of design demand attention to such matters as hydraulics, combustion, heat balances and transfer, vaporization and condensation, counter-current operations, corrosion and the theory of cracking.

Under the heading of plant processing comes a knowledge of the various sections of plant, of cracking processes, natural gasoline, chemical and earth treatment, dewaxing and much besides.

This has all to be handled in six hundred pages, a task involving much compression and an ability to confine the matter to essentials which only practical knowledge can give. The text is supplemented by numerous tables and diagrams.

The author writes from Tulsa, to-day an important city in the centre of the Oklahoma oil-field, though it was non-existent a few years back: he has had the help and advice of many of the well-known men in oil technology.

Physico-chemical Tables

Landolt-Börnstein Physikalisch-chemische Tabellen

Fünfte, umgearbeitete und vermehrte Auflage. Ergänzungsband 3. Herausgegeben von Prof. Dr. W. A. Roth und Prof. Dr. K. Scheel. Teil 3, Hälfte 1. Pp. xvi+1815–2352. Teil 3, Hälfte 2. Pp. 2353–3039. (Berlin: Julius Springer, 1936.) 188 gold marks.

THIS volume completes the third supplement to the fifth edition of the well-known "Landolt-Börnstein" tables and makes available a mass of physical and chemical data including work published so late as March 1936. The growth of this standard work of reference demonstrates the remarkable expansion of the physical sciences in our time. The fifth edition was first published in 1923; it occupied two volumes and 1,695 pages. The first supplement appeared in 1927 with 919 pages, the second in 1931 consisted of two volumes and 1,707 pages, whilst the third supplement which began to appear in 1935 has grown to three volumes and 3,039 pages. Prof. Roth and Prof. Scheele, to whom we are indebted for this work, must feel the satisfaction of a great task well accomplished; at the same time they must view with some dismay the probable dimensions of the next supplement in 1939–40.

The first two parts of the third supplement have already been reviewed in NATURE; this third part is concerned with data classified under the headings of electricity, magnetism, thermochemistry and thermodynamics. Only a few of the numerous tables can be mentioned. There are many new data on dielectrics, including a number of tables and diagrams on the properties of solid dielectrics. The section on electromotive force and on conductivity covers many pages, and a particularly valuable feature of this part of the volume is a series of tables of activity coefficients. This extends to more than thirty pages and gives values of γ over a range of concentrations for many aqueous and non-aqueous solutions. The growing interest in magnetism is reflected in the tables of new measurements of dia- and para-magnetic susceptibility, whilst the section on thermochemistry includes important new tables dealing with the energy of chemical bonds and the ignition temperatures of gases. The index covers the eight volumes of the complete work and is accompanied by an index of the properties of common substances.

The literature of science continues to grow at an ever-increasing rate, and presents a more difficult and complex problem in each generation to those who construct really comprehensive works of reference. The mere size of these tables, which deal only with numerical data in two related sciences, helps one to apprehend the magnitude of the general problem of the indexing of scientific literature, upon which much has been written both in NATURE and elsewhere. The team of devoted workers who under the direction of Prof. Roth and Prof. Scheele have brought into being this third supplement to "Landolt–Börnstein" have rendered a notable service to science and to industry all over the world.

Works of this kind must of necessity be expensive, but the increasing cost of these tables has been felt even by colleges and institutions, and is a very heavy burden on those who maintain a private library. It is therefore pleasant to find this last volume accompanied by a pamphlet announcing the twenty-five per cent reduction in price to countries outside Germany, with the exception of Switzerland and Palestine, to which German books are now subject.

S. S.

Psycho-Analysis and Social Psychology

By Prof. William McDougall. Pp. ix+207. (London: Methuen and Co., Ltd., 1936.) 7*s*. 6*d*. net.

PROF. MCDOUGALL says in his preface that he has "returned to the always interesting, but generally quite futile, task of criticizing the teachings of Professor Sigmund Freud and his school. . . . I have realized too late that I might have done much more for my chosen science, had I from the first spoken with a less modest voice. It seems to me probable that, had I at the outset put forward my views in a more self-assertive and clamant fashion, I might have been acknowledged as the leader of a powerful and perhaps dominant school of psychology; instead of remaining a well-nigh solitary outsider playing a lone hand".

Such a personal note, in the preface and even more in the three Lectures (delivered in the University of London, May 1935) which form the nucleus of the book, rather impedes the author in a critical handling of his subject. He holds that Freud is right in regarding human nature and behaviour as always and everywhere purposive, conative, hormic, but that in almost everything else Freud is in confusion or in error. On several points, the author makes pertinent criticisms, particularly in respect to the 'death-instinct' about which Freud himself writes with scepticism, though nothing constructive is offered in their place. But the concepts of unconscious mental processes which affect not only neurotics but also normal people; of the persistence of infantile modes of thinking in this unconscious part of the mind; of an *interplay* between loving or tender and aggressive or destructive impulses which only slowly reach stability; the important part played by anxiety and guilt in the development of the personality, particularly in infancy—these and other characteristically Freudian concepts are either profoundly misinterpreted in the author's exposition, or ignored.

An understanding of social psychology is an urgent need at the present time, for never has propaganda been so rapid and intense as in Europe to-day. It is a matter for great regret that the opportunity offered to a pioneer in social psychology by a university and by publication should have been spent in a "futile task" rather than in developing the present state of knowledge by addition to theory or by new observation. JOHN RICKMAN.

Aural Therapy in Relation to Deafness

By Prof. D. F. Fraser-Harris. Pp. 45. (London: The Sterling Medical Publishing Co., n.d.) 7*s*. 6*d*.

THIS little book, which is introduced by forewords from Sir James Purves-Stewart and an anonymous professor of the faculty of medicine in an English university, consists of six chapters. In the first, in which a short account is given of the varieties of deafness, the author points out that deafness is very rarely the result of a direct infection of the central organ of hearing but is nearly always the secondary result of generalized infections, such as measles, scarlet fever, typhoid fever, rheumatism and some forms of catarrh of the nose and throat.

In the second chapter the various causes of deafness are described, such as obstruction in the external ear by a polypus or wax, perforation of the tympanic membrane and otosclerosis. In the third chapter, which is devoted to the diagnosis of deafness, a description is given of the audiograph, an instrument designed for the accurate measurement of sound. The result of its use has been that with certain exceptions the various types of deafness have been found to present characteristic audiographic charts of their own, which are reproduced. The remaining chapters are concerned with treatment, especially by hearing aids and the thermal catheter.

In conclusion, the author acknowledges the indebtedness of otology to the physicists who, from the time of Graham Bell, by their intensive study of the measurement of sound, have rendered possible the delicate acoustical instruments which have so advanced otology.

Biological Time

By Lecomte du Nouy. Pp. x+180. (London: Methuen and Co., Ltd., 1936.) 7*s*. 6*d*. net.

THAT the biological aspects of the conception of time form a real problem cannot be doubted. Even the expression 'biological time' may have a meaning, if judiciously defined. The present book is built around three experimental facts closely connected with the flow of time: (1) the very regular falling off in the rate of healing (the cicatrization index) of wounds according to the age of the organism; (2) the regular fall in the growth-promoting power of serum for explanted cells with the age of the donor; and (3) the dependence of the subjective estimation of time on experimentally alterable factors, especially temperature. The book, however, has many disadvantages. At least one third of it is not at all germane to the principal issue, and in many places we miss citations of the relevant literature, even where it is French, the language in which this book was first published. It is concluded, *inter alia*, that there is a physiological time which does not flow uniformly like physical time, and that time has a discontinuous or atomic nature. The book is unfortunately marred by numerous errors of translation which in some cases may lead to confusion.

Television Optics:

an Introduction. By L. M. Myers. Pp. x+338. (London: Sir Isaac Pitman and Sons, Ltd., 1936.) 30*s*. net.

IN view of the many discursive books on the practice of television, this text is opportune, in that it sets out for the first time in book form the relevant physical data on lenses, Kerr cells, and electron focusing, and the relative effectiveness of various methods of scanning. More significant is its scientific accuracy and completeness; no important detail seems to be omitted which has a bearing on the optical performance of the many types of system. With its extensive bibliography and logical layout, Mr. Myers's book should prove to be a very valuable source of reference for students for many years to come.

L. E. C. H.

The Spectroscope and the Atom*

By Prof. Alfred Fowler, C.B.E., F.R.S.

IN his Thomas Hawksley Lecture of 1932, Lord Rutherford recounted the experiments with atomic projectiles which had given so much insight into the structure of atomic nuclei. My principal aim now will be to indicate how the spectroscope has contributed to our knowledge of the systems of electrons surrounding the nuclei of atoms, on which chemical and other properties are dependent.

Spectrum of Hydrogen

The simplest spectrum of all is that of hydrogen, showing the well-known Balmer series of lines in the visible region, in which the wave-numbers, ν, are represented by the formula,

$$\nu = R\left(\frac{1}{2^2} - \frac{1}{n^2}\right)$$

where $n=3$, 4, and so on, and the *Rydberg constant* $R=109,678$ as calculated from the lines themselves.

Other series of hydrogen lines similar in appearance to the Balmer series were afterwards discovered, and it was found that the entire spectrum could be represented by the general formula

$$\nu = R/n_1^2 - R/n_2^2 \text{ when } n_1 < n_2.$$

$n_1=1$, $n_2=2$, 3, . . ., gives the Lyman series in the extreme ultra-violet; $n_1=2$, $n_2=3$, 4, . . ., the Balmer series; $n_1=3$, $n_2=4$, 5, . . ., the Paschen series in the infra-red, and so on. Theoretically, the number of series is infinite. The Rydberg constant R appears with slight modifications in the formulæ for series of lines in the spectra of elements other than hydrogen.

It is of special importance to note that the wave number of each spectrum line appears as the difference of two other numbers. These are the so-called *spectroscopic terms*, each of which, in accordance with Bohr's theory, is proportional to a particular energy state of the atom.

Series in other Spectra

Similar regularities occur in the spectra of elements other than hydrogen. Many of these spectra are built up by a number of superposed separate series, illustrated for lithium and sodium in Fig. 1. Four of the series have received special names—*principal*, *sharp*, *diffuse* and *fundamental*, respectively.

As in the case of hydrogen, each of the abovementioned series may be represented by the differences between a spectroscopic term representing the limit of the series and a *sequence of terms* given by a running number. In the simple form adopted in the classical work of Rydberg, a term R/n^2 in the formula for hydrogen is replaced by $R/(m+a)^2$, where m stands for a sequence of integers and a is a fraction special to the particular series. It is found that the different series are closely related to each other, so that the limit of one series is a member of one of the other sequences of terms. The sequences, as distinct from the lines, are named S, P, D, F, after the series in which they occur. If the first terms of the S, P, D sequences are assigned the number 3, as would be the case for sodium, the relations between the series may be shown as follows:

Principal series . .	$3S - nP$	$n = 3, 4, 5, \ldots$
Sharp series . .	$3P - nS$	$n = 3, 4, 5, \ldots$
Diffuse series . .	$3P - nD$	$n = 3, 4, 5, \ldots$
Fundamental series .	$3D - nF$	$n = 4, 5, 6, \ldots$

where n is known as the *principal quantum number*. The actual numbering of the terms in modern form is based upon theoretical considerations.

As first recognized by Ritz and expressed in his *combination principle*, other terms of a sequence besides the first may combine with terms from other sequences to produce subsidiary series, as, for example, $4P-nD$. The possible combinations in ordinary circumstances, however, are restricted by selection rules, one of which is that only terms from adjacent sequences in the order S, P, D, F, G, . . . combine to produce lines.

Multiple Terms

When a family of series consists of doublets or triplets, the specification of the spectroscopic terms requires additions to the scheme for a singlet system. These are the so-called *inner quantum numbers*, j, which were empirical in the first instance but have since become of profound theoretical importance. In modern form, the different types of terms are written as follows:

---

* From the twenty-third Thomas Hawksley Lecture of the Institution of Mechanical Engineers, delivered on November 6, 1936.

Singlet terms .	$^1S_0$	$^1P_1$	$^1D_2$	$^1F_3$
Doublet terms .	$^2S_{1/2}$	$^2P_{3/2}$	$^2D_{5/2}$	$^2F_{7/2}$
		$^2P_{1/2}$	$^2D_{3/2}$	$^2F_{5/2}$
Triplet terms .	$^3S_1$	$^3P_2$	$^3D_3$	$^3F_4$
		$^3P_1$	$^3D_2$	$^3F_3$
		$^3P_0$	$^3D_1$	$^3F_2$

Here the index on the left of the symbol for each term indicates the multiplicity r of the system, while the suffix on the right is the inner quantum number j.

Terms of higher multiplicity than three occur in many spectra, giving quartets, quintets, sextets, septets, octets, or still greater complexities. Odd and even multiplicities, however, never appear together, but occur alternately in passing through successive groups of elements in the Periodic Table. As many as three systems may occur in the same spectrum. The names given to these higher multiplicities indicate the *maximum* number of j values assigned to any of the terms. S terms are always single, P terms have never more than three components, D terms not more than five, F terms not more than seven, and so on.

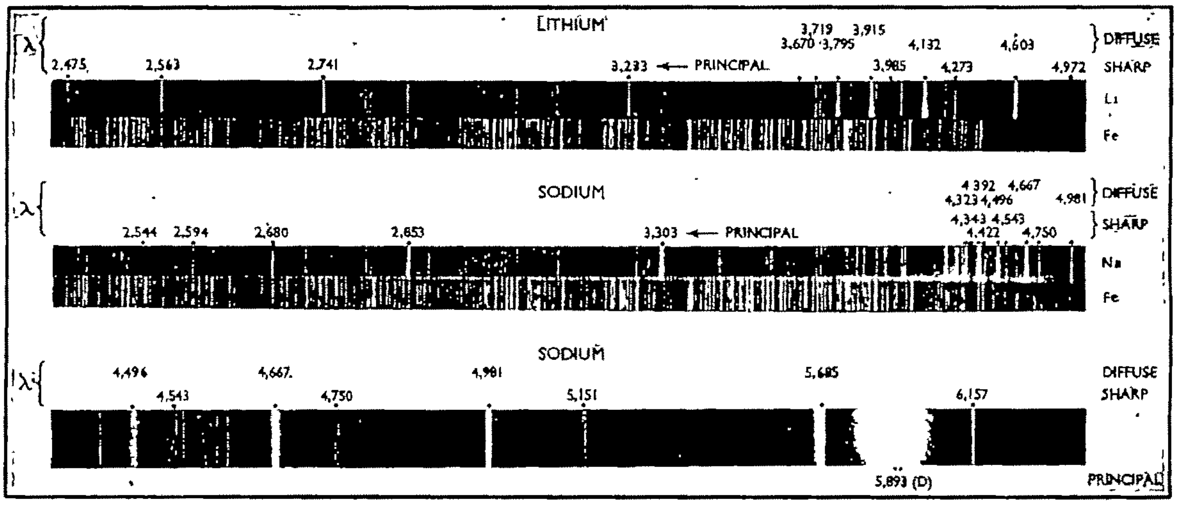

Fig. 1.

Series of lines in the spectra of lithium and sodium with iron arc comparisons.

Under ordinary conditions, combinations between different terms in the same spectrum are subject to two further selection rules, namely, $\Delta r = \pm 2$ or 0, and $\Delta j = \pm 1$ or 0, with $j=0$ to $j=0$ forbidden. This means that terms cannot combine to produce a line unless the r values differ by 2 or 0 and the j values by 1 or 0. The first selection rule already mentioned is expressed as $\Delta l = \pm 1$, where $l = 0, 1, 2, 3, \ldots$ for S, P, D, F, . . . terms.

Bohr's Theory

The significance of series of lines in spectra had not begun to be understood until Bohr launched the epoch-making quantum theory of atomic spectra in 1913. The normal hydrogen atom was assumed to consist of a minute nucleus of mass M and positive charge E, with a single electron of mass m and negative charge e moving round it. When the atom was excited by the absorption of energy, the electron was supposed to traverse larger orbits, specified by the quantum condition that the angular momentum must be an integral multiple of $h/2\pi$, where h is Planck's constant. On the further assumption that a quantum of radiation $h\bar{\nu}$ (where $\bar{\nu}$ = oscillation frequency) was emitted when the electron returned from one orbit to another of lower energy, Bohr derived an expression for the hydrogen spectrum which is in agreement with that determined experimentally, and in which R took the form, $\frac{2\pi^2E^2e^2}{ch^3} \cdot \frac{Mm}{M+m}$, where $E = e$ for hydrogen and c is the velocity of light.

A *term* represented an energy state of the atom, giving no radiation, and a *line* the emitted radiation when the atom passed from a state of higher to one of lower energy. This has been found to be applicable to all atoms, and the different states are regarded as *energy levels*, quite irrespective of any particular model of the atom.

Ionized Atoms

Strong support for the theory was given by its application to the spectrum of ionized helium, which is produced by intense electrical discharges through the gas. This spectrum is developed when the atom has lost one of its electrons, the remainder then being similar to a hydrogen atom, except that the nucleus has a double positive charge, and a mass four times greater. The spectrum should accordingly be similar to that of hydrogen, but relatively displaced, and this agrees with observation, even in quantitative details. Following this, it was foreseen that an atom of any element might be deprived of its electrons one by one through increasing excitation, and that the series constant would change through values of approximately $4R$, $9R$, $16R$, and so on, until, when only one electron remained, the spectrum would become similar to that of hydrogen. All this has been verified by experiment, and, as was expected, it has been found in general that when an atom has become ionized its spectrum resembles that of the element which precedes it in order of atomic number. If two electrons have been removed, the spectrum will resemble that of the element of atomic number $Z-2$, and so on indefinitely. It has been found convenient to represent the spectrum of a neutral atom by ZI, and the spectra at successive stages of ionization by ZII, ZIII, etc , the corresponding states of the atom itself being indicated by Z, Z^+, Z^{++}, etc

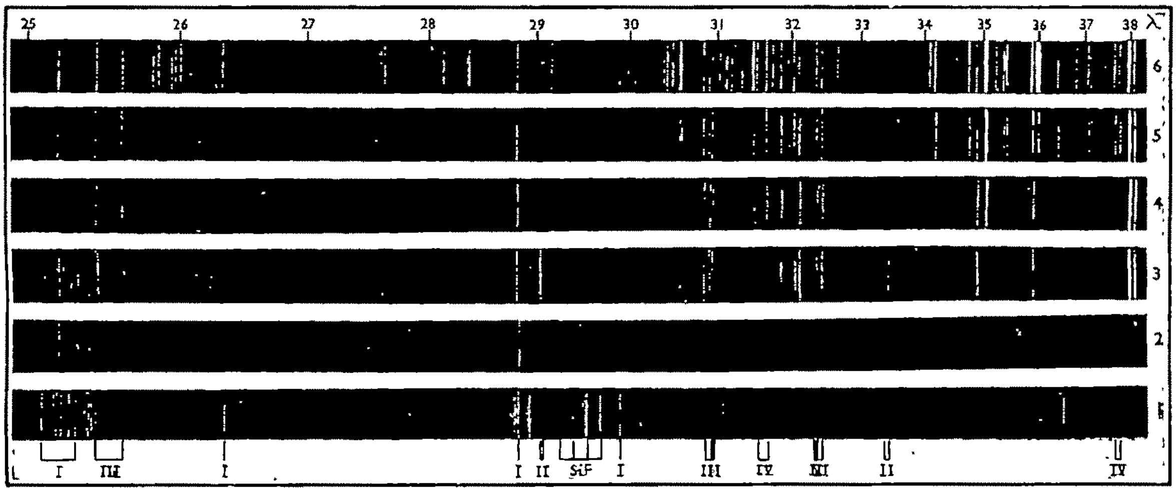

Fig. 2

SUCCESSIVE SPECTRA OF SILICON PRODUCED BY GRADUALLY INCREASING INTENSITY OF DISCHARGE THROUGH A VACUUM TUBE CONTAINING SILICON TETRAFLUORIDE.

A good illustration of the changing spectrum of an element is given by the photographs of silicon spectra reproduced in Fig. 2. The experiments were made on the vapour of silicon tetrafluoride in a vacuum tube, the intensity of the electric discharge increasing gradually from 1 to 6.

THE VECTOR MODEL

As the finer details of spectra were taken into consideration, the Bohr conception of the atom was found to require more elaboration. For an explanation of multiple terms, for example, it became necessary to suppose that the electron possessed a spin, the angular momentum of which, denoted by the quantum number s, was fixed at $\pm\frac{1}{2}$, according to the direction of rotation.

Despite such additions, however, it was ultimately realized that the orbital model was incapable of describing all the intricacies of spectra, and in more general considerations it was displaced in favour of a *vector model*, in which the various quantum numbers of the electron were no longer necessarily associated with orbits, but with angular momentum vectors the interpretation of which in the form of a picturable mechanism was not essential. In this model, five quantum numbers are used, n, l, s, j, and m, but only four of these are independent, since j is the quantized resultant of l and s. In the simpler cases in which the orbital model is adequate, these vectors correspond respectively with the quantum numbers n, l, s, and j already described; while the number m corresponds with the quantized projection of j along the magnetic axis of the atom. In the general case, however, although the names suggested by the orbital conception are often used, they cannot be applied with their literal meanings, and the quantum numbers are used in calculations merely as symbols obeying certain rules.

It is not possible here to enter into intricate details of spectra. It must suffice to state that on the supposition that an atom is so constituted that the angular momenta of all the rotary motions can only change by unit steps, a complete scheme has been worked out by Hund by which the types of terms associated with a given distribution of electrons around the nucleus can be calculated. The results of such calculations are in entire agreement with the types deduced from the numerous analyses of spectra which have now been made.

QUANTUM MECHANICS

These developments of the theory of atomic structure took place in intimate relation with spectroscopic research. The result was a conception of the atom, definite so far as application to experimental results was concerned, but containing basic *ad hoc* assumptions which violated the principles of classical mechanics. Throughout the development of the theory it was evident that some fundamental system of mechanics was required from which the assumptions of the existing quantum theory would follow as natural consequences.

The foundations of such a system were laid by Heisenberg, de Broglie and Schrödinger, and what is probably the most fundamental statement of the resulting quantum mechanics has been given by Dirac. In the derivation of this system, the knowledge gathered from the analysis of spectra has been supplemented by that obtained from other experimental work. It would therefore take us outside the scope of our subject to enter into these advances, and it only remains to indicate in general terms the reaction of quantum mechanics on the question of atomic structure. This may be summed up by the statement that, while the arbitrary postulates of the empirical theory have been expressed as necessary consequences of fundamental mechanical principles, the orbital picture and vector representation of the atom have been discarded, and no equally picturable substitute has been given. A partial picture is possible in terms of a rather indefinite distribution of electricity, one such distribution corresponding to each stationary state, or electron configuration, of the atom according to the earlier ideas. It is impossible, however, to locate the electron at a precise position in this distribution.

Nevertheless, for the practical purposes of spectroscopy, the vector model retains its usefulness. Many of the results obtained by its application are identical with those given by quantum mechanics, and where divergence occurs, a simple modification—as, for example, the substitution of $\sqrt{l(l+1)}$ for the l of the vector model—produces close agreement. The vector model is likely, therefore, to remain as a guide to spectroscopists for some time to come.

University of Heidelberg and New Conceptions of Science

From a Correspondent

THE general character of the changes in the German universities was expounded by Herr Rust, Reichsminister for Education, at the recent celebration of the 'jubilee' of the University of Heidelberg. His address is translated in the November issue of the *Universities Review*. Herr Rust believes the New Germany to be the true heir of Sparta and suggests that these changes are as though Sparta had triumphed over Athens. Had that calamity befallen the world, all that we could have inherited from Greece would have been 'discipline', for Sparta had no other gifts to bestow. But the new "Weltanschauung", Herr Rust assures us, "is the life-blood of a new science . . National Socialism has provided science with new principles from which she can derive the strength of self-confidence. . . The old idea of science based on the belief in the supremacy of the intellect is finished."

The effect on a university of the arbitrary treatment of its staff is not numerically expressible. Injustice to one teacher may overawe the entire faculty and deprive its work of all value. Staff changes at Heidelberg tell, therefore, of only a fraction of the injury to learning. We give, however, a summary of what has happened at Heidelberg; and it suggests what is going on throughout the universities of Germany.

The calendar of the University of Heidelberg for the academic year 1936–37 may be compared with that of 1932, the last year unaffected by the new regime. The historical account of the university, which opened previous calendars, is omitted this year. Any record of either benefactors or distinguished alumni would have to include names of many of Jewish or partly Jewish origin. The very title of the official head has been altered, and Rector Groh is now Führer Groh. The order and many of the titles of the staff are changed. After Führer Groh follows the *Leiter* of the body of dozents, Herr Schlüter, who, oddly enough, is not himself a dozent. Next is the undergraduate Herr Ernst Kreuzer, who is both a member of the Senate and "Officially designated Undergraduate Leader at

Heidelberg of the Nazi Student Union of the Nazi Party". (*Kommissarischer Hochschulgruppenführer der Hochschulgruppe Heidelberg des NSD Studentenbundes der NSDAP.*) After this student follow the deans and other members of the Senate. Six of the ten ordinary members and seven of the twelve deans and sub-deans were not members of the teaching staff in 1932. The academic authority that occupies the next place is the "Nazi Teachers' Union" (*Nationalsozialistische Dozentenbund*). Of this the "District Führer" (*Gaudozentenbund-Führer*) is Party Member Professor Dr. Ernst Krieck who, for a short time, held uneasily the rectorship of the University of Frankfort. The promotion of Dr. Krieck, not long ago teacher in a *Mittelschule*—that is what we should call the 'modern side' of a secondary school—has been very rapid.

There were 215 teachers at the University in 1932. There are now only 180*. Of these, 99 survive from the old regime, while 81 have come in with the new regime. The displacements do not imply promotion. On the contrary, many higher positions are now occupied by previously unknown men, and some by men who hold, in addition, ministerial office (*Ministerialrat*), a combination forbidden under the old regime. Nazi influence is most evident, however, in the lower ranks of university teachers, the list of whom teems with 'Party Members'. A few teachers have been permitted to keep nominal positions but deprived of stipend. Among those dismissed are, remarkably enough, a number who have been added to the staff since the advent of the present regime. The career of a professor in Germany has become, like the life of Hobbes's primitive man, "poore, nasty, brutish and short".

The actual causes of dismissal have not been published, and to ascertain them with accuracy would involve a long and a dangerous research. In the majority of cases doubtless the victim was a Jew or had some more or less distant Jewish affiliations. Nevertheless, in the Faculty of Medicine, where dismissals have been most numerous, only half of the dismissals seem explicable on such grounds. "Political unreliability", that is to say, connexion with any 'left' party before the advent of the present regime, or want of submissiveness to the present regime, is a common cause of dismissal. It is difficult to say in how many cases dismissal has been produced or stimulated by direct action by the students. These have violent national socialist leaders, and there can be no doubt that they have had and have a large share in the control of the University.

The constitution of the reduced staff may be learned from the following table:

Faculty	Percentage of new appointments
Science	31
Theology	36
Law	38
Philosophy	49
Medicine	56

The changes in the Faculty of Law are peculiarly significant. The Institute for Historical Jurisprudence has lost its former name "Rudolf-Mosse-Stiftung", which indicates that it is a Jewish benefaction. The Jewish endowment is retained. Important fields of legal knowledge are no longer represented. In the list of 1935–36 the subject of "International Law" still appeared under the reduced dignity of "Foreign Law" (*Ausserstaatliches Recht*) to be expounded by one undesignated. In the current list it has vanished and left not a wrack behind. A subject which makes its first bow to the learned public is "Reform of the Penal Law", but no room is found for "Penal Law" itself. The hand of the secret police is here discernible. Special instruction is provided in "Recent Political History", "Folk Elements in Law" (*Rechtliche Volkskunde*), "Family Heredity", "Folk and Race", and "German Military Law".

In the Philosophical Faculty there are new courses by new men on "Foundations of National Socialist Philosophy" as well as on "Folk Philosophy", "German Philosophy", "Educational Policy", "The Nature of the Folk Community", and "The Nature of Ancient German Religion". The Philosophical Faculty has now a new "Professor of Modern War History". His work would seem to overlap that of Herr Minister Schmidthenner, who is "Professor Ordinarius of History with special reference to the History of War and Military Knowledge" (*Wehrkunde*). Herr Professor Minister Schmidthenner will lecture on "The World War", "Politics and War Leadership", "The Total War", "Germany's Right to Colonies" and on "Political Geography of the German East". He holds a seminar on "Being and Action of the German Soldiery".

In the Faculty of Science the following are among the dismissed: the two ordinary professors of mathematics, Liebmann and Rosenthal, the professor of geology, Salomon-Calvi, honorary Professor Victor Goldschmidt, Extraordinary Professors Merton (Zoology) and Gerta von Ubisch (Genetics), Privatdozents Lemberg, Wolf and Schmitz. There is now no ordinary professor of mathematics at Heidelberg. Many courses in mathematical subjects are suspended or advertised as by teachers as yet undesignated.

---

* The number of teachers is approximate. As in an English university, many members, for example, librarians, junior demonstrators or physical instructors, belong doubtfully to the teaching staff. The figures 215 and 180 are conservative.

In the Faculty of Medicine the dismissals have been very numerous. Among them are Ordinary Professors Baeyer, Bettmann, Blessing, Sachs, Willmanns; Honorary Professors Fränkel and Löwe; Extraordinary Professors Gruhle, Gyorgy, Klopstock, Meier-Grosz, Münter, Schreiber, Serr, Steiner, Zade; Privatdozents Laser, Pagel, Stern, Strauss, Wittebski and Wurm. Nearly the whole of the cancer research staff has been dismissed. The first medical lectures advertised are "Nazi Philosophy and Race Theory", "Folk and Race", "Medical Outlook on Physical Development", "First Aid with special reference to Military Sport and Gas Defence".

We cannot discuss student life at Heidelberg, but note that before matriculating a student must produce documentary evidence of the religion of both of his parents and of his four grandparents. The recession of learning and the significance of propaganda in the life of the University is revealed in the programme of the official "Students' Faculty Discussion Groups" (*Arbeitsgemeinschaften*). Subjects for debate there are "Self-consciousness of German Culture", "Education of Nazi Youth", "Labour Service and Military Law", "Claims of the Germans in Czecho-Slovakia", "Laws concerning Race", "Care for Healthy Inheritance", "Eastward Expansion of Germany", and "Professor Lenard and his Significance for German Science".

Faced with a series of unprecedented attacks on the interest of learning as well as on their own rights, no member of the staff has had the temerity to utter any word of public protest. There are several retired or very senior members of independent standing from whom one might have reasonably hoped for some sign of courage. But Germany has openly reinstated serfdom, the essence of which is to restrain the worker from marketing his labour as he will and to place him at the disposal of an overlord. It is, therefore, appropriate that the minds of Germans should be enslaved along with their bodies, for slavery mercifully provides its own spiritual anæsthesia. This, in truth, is the 'new principle' for science which Reichsminister Rust has discovered. But, to speak yet more plainly, science has been abolished in the German universities and its spirit has abdicated from the Reich.

Obituary Notices

Dr. A. A. Robb, F.R.S.

ALFRED ARTHUR ROBB, who died on December 14 at the age of sixty-three years, won distinction by his contributions to the theory of relativity during the early period of its development. His life-work is contained in a book "A Theory of Time and Space" first published in 1914; it is a happy circumstance that he lived to complete a revised edition which appeared a few months ago. This work consists of an axiomatic and logical development of the geometry (Minkowskian geometry) of the space-time of special relativity theory, arranged as a sequence of more than two hundred theorems. It is generally recognized to be a model of its kind.

To the analyst, the difference between Euclidean and Minkowskian geometry seems trivial, being merely the substitution of an imaginary for a real variable in one of the co-ordinates; but the formal simplicity of the change often causes insufficient attention to be paid to its implications, so that serious misconceptions arise later on. In an axiomatic treatment, the two geometries show little resemblance to one another; in particular, Robb's theory could not be applied to Euclidean space, nor could anything even remotely analogous be substituted. His work shows more clearly than any other how by dissecting space-time into spatial sections we lose the very essence of its constitution. Robb developed his theory on the sole basis of an irreversible relation of 'before' and 'after', which, as he pointed out, is simpler than the spatial relation of 'between'. This leads to the study of a type of order of points which he called 'conical order'. His work, which he attributed to the inspiration of Sir Joseph Larmor, was partially independent of that of Einstein and Minkowski; and, coming at a time when their theories were little known or discussed, it has been very helpful in elucidating the paradoxes that seemed to arise.

There was an unusual combination of the abstract and the practical in Robb's mental outlook. He took great trouble in designing models to illustrate his theory. Apart from relativity, he was interested in geometry and mechanics, not in a systematic way, but on the look-out for neat devices, subtleties and curiosities. He delighted in exposing the traps which catch unwary text-book writers, and was rather merciless to the victims. It was difficult to persuade him that a man might have a sound understanding of relativity in spite of his having described a geodesic in space-time as a track of minimum (instead of stationary) length. He was no less severe on those who too unguardedly assert the equivalence of electric circuits and magnetic shells, producing to confound them the example of a circuit bounding a surface which has only one side. But if he had to some extent the 'gadget mind', he had also exceptional critical insight and logical power. To discuss a problem with Robb was most stimulating; and he seldom failed to find some new angle leading to clearer vision. Being shy and reserved, he made comparatively few friends; but those whom he had, found him a most entertaining companion. They appreciated also his extreme conscientiousness and sense of duty. He was a man of strong convictions, which he urged with pugnacity tempered by a delightful sense of humour.

No account of Robb would be complete without reference to his gift for writing topical verse and parody. He wrote many of the songs sung at the annual dinners of the Cavendish Society. His feat of adapting Maxwell's equations as the chorus of a song must have earned the gratitude of many who, like the present writer, could never remember them otherwise.

Robb was a thorough Irishman, in voice, appearance and sentiment. Though his home and family connexions were in Belfast, his sympathies were generally with the South. After passing through Queen's College, Belfast, he became a research student at St. John's College, Cambridge; he afterwards studied at Göttingen, where he took a Ph.D. degree. Being possessed of independent means, he never sought a post; but his habit was to spend most of term-time in Cambridge, living very quietly in lodgings, seeing a few old friends, and mainly occupied with mathematical research.

When the Great War came, Robb voluntarily undertook chemical work in connexion with the supply of medical drugs. But after some time his suspicions were aroused, and being unable to obtain an assurance that his products were not intended for the production of poison gas, he resigned. Not to be deterred from medical service, he learned to drive a motor-car and served as an ambulance-driver in France. In later years he joined Emmanuel College and was made a member of the High Table. Sometimes by invitation of the Faculty Board of Mathematics he gave a course of lectures on his theory. He was elected to the Royal Society in 1921.

This quiet academic life was rudely broken about five years ago, when Robb was called by circumstances to assume the management of his family business—an important firm in Belfast. Through a series of deaths of near relations, he was left almost the sole adult representative of his family, and it depended on him to keep things going in the interests of the next generation. For him it was a most uncongenial change; but he appears to have adapted himself to it successfully. He retained his rooms in Cambridge, hoping to find opportunity to return; but his visits have been rare. The new edition of his book, which contains considerable changes, is evidence that he remained active in mathematical research up to his death.

A. S. E.

Sir Henry Hall, I.S.O.

It is with great regret that we have to record the death of Sir Henry Hall, who died at Brookside, Chester, on December 8, at the ripe age of ninety years; he was born, therefore, in 1846, and was the youngest son of Mr. John Hall, of Sedgefield, Co. Durham. He served his time at the old Haswell Colliery Co., Durham, and got an appointment in the Swansea district in 1873. About 1875 he was appointed inspector of mines in that district, and was afterwards transferred to Lancashire, and was in addition given the care of North Wales when districts were reorganized a few years later (about 1910).

According to his own account, an accident at Wynnstay Colliery, North Wales, about the year 1874, first directed Sir Henry's attention to the danger of coal dust, and in 1890 he was appointed to experiment on the subject by the Royal Commission, which sat under the Right Hon. Joseph Chamberlain, M.P., as chairman, and consisted of a number of men well versed in explosions and mining, who altogether examined thirty-nine witnesses. According to his own statement, three different collieries were experimented on, in shafts ranging from 50 yd. to 200 yd. deep, and in a gallery some 45 yd. deep, using dust from the various districts of the country and no firedamp. It was not a new idea of Mr. (as he then was) Henry Hall's, the original idea being due to Faraday and Mr. Lyell, according to Mr. Godfrey Lushington (in Answer 66) in 1844. It was then revived by Mr. William Galloway and Messrs. W. N. and J. B. Atkinson, in which an explosion in a hopper, where no firedamp was present, was cited.

Mr. Henry Hall's results were accepted by the industry, but his remedies for this state of affairs, namely, watering and the use of high explosives (not gunpowder), were not followed up, because watering was not a complete remedy and often produced 'creep', and Sir William Edward Garforth's further experiment on the use of stone dust, finely divided, has been accepted by the industry in general and is now confirmed by legislation. The remedial suggestion decidedly advocated by Mr. Henry Hall was the use of the safety lamp, according to Mr. J. B. Atkinson, which has since been made compulsory by legislation.

For this service and his numerous papers read before the North of England Institute of Mining and Mechanical Engineers, and before the Institution of Mining Engineers—these among other services to the mining industry—Hall was given the medal of the Institution of Mining Engineers in 1928, whilst he was awarded the Imperial Service Order, and afterwards received the honour of knighthood. His death removes a man whose name is a household word in the mining industry, and who has ever, even after his retirement from the inspectorship, taken the keenest possible interest in the industry.

Dr. E. S. Cobbold

The ranks of the amateur geologists have been seriously thinned by the death of Edgar Sterling Cobbold on November 20, in his eighty-sixth year. The son of a surgeon who was greatly interested in natural history, he studied engineering at the Owens College and, after some fifteen years' practice, retired to Church Stretton in 1886. Here he at once threw himself into the study of the district, taking an active part in the proceedings of local natural history societies, and contributing extensively on archæology and geology to both scientific and popular guides to the area.

Cobbold's first contribution to geology here was the description of a Silurian outlier of much tectonic significance under Caer Caradoc. He soon came under the spell of the thoroughness and accuracy of Charles Lapworth's work, and became infected with his enthusiasm for the ancient rocks. Lapworth's discovery of the *Olenellus* fauna in Shropshire, and Groom's find of *Paradoxides*, having demonstrated the existence of Lower and Middle Cambrian rocks in the Stretton and Wrekin areas, Cobbold proceeded to collect from these rocks inch by inch. His reward was the discovery of many forms new to Great Britain and to science. He described a dozen new genera and more than a hundred new species from them, and was able to divide the Lower Cambrian into eleven, and the Middle into nine divisions, mostly definite life zones.

Thus Cobbold made his area the type-section for Britain, correlated the rocks with those of America and the Continent, and demonstrated the existence of breaks in the sequence caused by earth movements. He became our leading authority on Cambrian faunas, and was called in by the Geological Survey to determine the fossils collected by himself and others from the considerable Cambrian area between the Wrekin and Charlton Hill. His type-fossils have been lodged in the British Museum, the Geological Survey Museum, or the Sedgwick Museum.

The work that Cobbold accomplished with such conspicuous success could only have been carried out by one living on the spot, with abundant leisure and the knack of using it effectively, with remarkable energy, industry, devotion, and perseverance, with wide knowledge of his subject and its literature in many languages, and with the hand and eye of an artist.

W. W. W.

We regret to announce the following deaths:

Mr. Thomas Crook, O.B.E., since 1928 principal of the Mineral Resources Department, Imperial Institute, London, on January 6.

Mr. P. A. Ellis Richards, president of the Society of Public Analysts in 1922–23, aged sixty-eight years.

Sir David Semple, founder and first director (1900–5), of the Pasteur Institute of India on January 7, aged eighty years.

News and Views

Prof. E. B. Bailey, F.R.S.

The Lord President of the Council has appointed Prof. E. B. Bailey, professor of geology in the University of Glasgow, to be director of the Geological Survey of Great Britain and of the Museum of Practical Geology, a post rendered vacant by the untimely death last year of Dr. Bernard Smith. Prof. Bailey previously served on the staff of the Survey for some twenty-seven years. After a distinguished career at Cambridge, where he gained the Harkness scholarship in geology, in 1902 he was appointed geologist to the Geological Survey of Scotland, with headquarters in Edinburgh, where he remained until 1929. During the years he served in Scotland, Prof. Bailey made a special study of the tectonics of the Dalradian schists, a subject in which he became an acknowledged leader. He also took an important part in the survey of the tertiary igneous rocks in Mull, and edited the Survey memoir on this area. Other duties carried out during his years on the Survey included much work on the Carboniferous rocks in the Midland Valley of Scotland. His experience was further widened by visits abroad from time to time. Prof. Bailey's Survey career was interrupted by the Great War, during which he saw much service in France with the Royal Artillery, receiving the Military Cross, the Legion d'Honneur and the Croix de Guerre as rewards for distinguished services. His enthusiasm for geology was such that he even found time to publish papers on this subject during the time he was engaged on military service.

In 1929, Prof. Bailey resigned from the post of district-director in Scotland, to take up his appointment to the chair of geology in Glasgow. During his tenure of this post, he has continued his researches into Highland tectonics, and has also developed the application of current- and graded-bedding to the question of the age of the Highland schists. Among the academic and other distinctions received by Prof. Bailey may be mentioned the following: from the Geological Society of London, in 1923 the Bigsby Medal, and in 1935 the Murchison Medal; in 1928, president of Section C (Geology) of the British Association; in 1930, elected fellow of the Royal Society; in 1936, awarded the honorary degree of D.Sc. by Harvard University at its tercentenary celebration. The results of the official work carried out by Prof. Bailey, and of his private researches, are contained in numerous memoirs of the Geological Survey, and in the publications of various learned societies. He is also the author of "Tectonic Essays: Mainly Alpine".

The Piltdown Jaw

In another column of this issue of NATURE (see p. 120) reference is made to the reaffirmation by Prof. F. Weidenreich of the Cenozoic Research Laboratory, Peiping, of the orang-like character of the Piltdown jaw, which he relegates to the group orang-chimpanzee-gorilla, standing outside the line of human descent. In this connexion attention may be directed to another attack on the human character of the Piltdown relic by Mr. Alvan T. Marston, which appears in *Discovery* of January. Here the basis of argument is the character and arrangement of the teeth, in which it is maintained the jaw is anthropoid and not human. The form of the canines, it is said, points to a gap between canines and incisors and an outside bite of the former, such as are found in the apes, but never appear in man, even in such an early and primitive form as Peking man. Similarly, such indications as are afforded by the Piltdown jaw on the order of eruption of the teeth point to the anthropoid, rather than the human, character of the dentition. The canine, instead of preceding the second molar, as in man, was here the last to erupt, and indeed, Mr. Marston infers, was still incompletely formed. Further, he concludes, the jaw shows no evidences of the adaptations for speech, for which capacity is to be inferred from the advanced character of the brain. When Prof. Weidenreich's promised monograph on the teeth of *Sinanthropus* appears, in view of the relatively large amount of evidence at his disposal, it may be anticipated that we shall learn whether the teeth show the variability, which he has found in the mandible, and whether it supports the evidence already available to Mr. Marston, on which he relies to no little extent in stating his case.

France and its People

IN "France: a Handbook for Beginners in French" (Cambridge: W. Heffer and Sons, Ltd. Pp. 48. 1*s*. net) are reproduced three lectures by Dr. Cloudesley Brereton, originally broadcast in Great Britain in December 1935 and January 1936 and afterwards repeated, at the invitation of the French Government, from Paris. The sub-title, in so far as it may tend to suggest that the pamphlet is unlikely to appeal to the general public, is misleading, for here is no mere catalogue of dry facts but a lively appreciation of the genius, to quote the author's own words, of a hard-working, cheerful, amiable, keen-witted, polished, social, artistic and, at bottom, spiritually-minded people. That it is eminently fitted to promote that mutual understanding and appreciation between nations which a strident modern nationalism threatens to stifle has been recognized by the judges entrusted with the awarding of the recently instituted "Prix internationaux du Tourisme". They have awarded to the author the second prize of 15,000 francs; the first prize, of 25,000 francs, having been awarded to Mrs. Brangwyn, an American, for "Everybody in Paris". As an example of Dr. Brereton's method may be quoted his comparison between French and English science teaching in secondary schools. Practical science is, he holds, rather neglected in the French *lycée*. "In the more abstract side of science, however, a very high standard is attained. Our schools possibly err in the other direction—somehow the glamour of science has rather been overshadowed by the excessive cult of the test tube in this country".

Archæological Expedition to Nubia

SIR ROBERT MOND's appeal on behalf of the archæological expedition to Nubia projected by the Egypt Exploration Society merits, and no doubt will receive, full measure of support. The valuable work of investigation which the Society has carried out at Tell el-Amarna under its present concession from the Egyptian Government, on a site which might have been thought already to have yielded its precious material to the excavator, is a warrant that the expedition will spare no pains on the new sites to secure that nothing of moment is overlooked which may throw light on the history and culture of this little-known part of ancient Egyptian rule. As Sir Robert points out in his letter to *The Times* of January 4, the two sites which have been reserved provisionally for the Society, Sulb (Soleb) and Sesebi in Upper Nubia in the region of the Third Cataract of the Nile, will both throw further light on the Amarna age, upon which the Society has been engaged now for some years. Their comparative inaccessibility accounts for the fact that they have been little studied; but it is known that at both these fortress cities there are remains which date from the reigns of Amenophis III and Akhnaton. The temple of Sulb is in fact described by Breasted, as quoted by Sir Robert, as "the most important monument surviving in the Sudan, and one of the two greatest architectural works surviving in the Nile Valley, the other being the temple of Luxor . . . We have in Soleb, therefore, one of the first creations of the Empire". As the temple has on its walls running reliefs which depict scenes from the Sed festival, to celebrate which Amenophis caused this temple to be built, its investigation will supply information as to ritual and belief which is unique. Further, as the two fortresses probably occupied the sites of earlier Nubian towns, some data, at least, should be forthcoming bearing upon the earlier population of Nubia, which, it will be remembered, the late Sir Grafton Elliot Smith held to be of considerable moment in the understanding of the early racial history of ancient Egypt.

Academy of Natural Sciences, Philadelphia

IN the course of the current month, the Academy of Natural Sciences, Philadelphia, will issue invitations to an international symposium on early man and the origins of the human race which is to be held in Philadelphia on March 18–20. This symposium will form part of the proceedings celebrating the one hundred and twenty-fifth anniversary of the foundation of the Academy. Among those who have already promised to contribute to the symposium are Dr. P. Teilhard de Chardin of China, Dr. Ralph von Koenigswald of Java, Dr. R. Broom of South Africa, Miss D. A. E. Garrod of Great Britain, and Dr. Kaj Birket-Smith of Denmark. The arrangement of the programme is in the hands of a committee which includes Dr. John C. Merriam, president of the Carnegie Institution, Washington, D.C., Dr. Edwin C. Conklin, vice-president of the Academy and president of the American Association for the Advancement of Science, Dr. George G. MacCurdy, director of the American School of Prehistoric Research, Dr. Hellmut de Terra of the Carnegie Institution and Dr. E. B. Howard, acting curator of the Academy's Department of Geology and Palæontology, who will act as secretary of the Committee. An attraction additional to the original papers which will be presented at the symposium is a "Hall of Prehistory" in which will be represented all the fossil remains of early man and his weapons and tools, as well as replicas of the principal sites of discovery. Among the exhibits for which arrangements have already been made is a cast of *Homo Modjokertensis*, the recent discovery from Java, which has been claimed to be "the earliest datable human fossil". This will be exhibited by Dr. von Koenigswald. Dr. E. B. Howard will be responsible for a reproduction of the site of Folsom man at Clovis, New Mexico, and casts of the recently discovered relics of Peking man will be shown by Dr. Teilhard de Chardin.

Wool Industries Research Association

AN apologia on a research association's work and policy is an unenviable task for any of its officials to essay. Mr. Wilsdon, director of the Wool Industries Research Association, in his recently issued annual report, has frankly stated those especial difficulties which beset his and other research associations in endeavouring to establish and increase the confidence and support of its members, whose subscriptions are on a voluntary basis, whose individual interests are widely divergent and, with the many subdivisions of the industry, even competitive, and whose expectations, apart from some particular information yielding direct financial benefit, are largely nebulous in character. Such associations are for these reasons an easy mark for destructive criticism, always louder than the praise for specific individual benefits, which is too often uttered unobtrusively, if at all. Standardization, on which Mr. Wilsdon rightly puts insistence, has an undoubted place within this, as other, industries. There is also much to be said in favour of pooling information for the general raising of manufacturing excellence; but there are limiting factors which make the effective bounds much narrower than in most manufactures. As the architect puts his individual skill and experience, as well as his knowledge of fitness of material, design and colour, into the creation of the structure, so is cloth-making largely a 'creation' in this sense. The devising of woollen blends and of worsted tops is of similar complexity, and such circumstances tend to narrow the field within which the personal factor can be replaced or even checked by scientific classification.

ON the other hand, the trade should give wholehearted adherence to the dictum that "research on the fundamental properties of the wool fibre is the surest way of maintaining its pre-eminence among the textile fibres". Of the two discoveries referred to, the neutral bleach and the new unshrinkable process for wool initiated by Prof. A. T. King, of the University of Leeds, while chief chemist of the Association, the latter now promises to take front rank in modern textile developments, but might well have languished in face of incredulity and prejudice in some quarters. The Director of Research and his committee are to be congratulated on having brought it to the point of imminent release, against the considerable inertia which revolutionary changes have to overcome. Discoveries of this kind, however, which cannot be expected to occur frequently, should not, as Mr. Wilsdon has cogently reasoned, constitute the only means of bringing conviction to the trade of the Association's usefulness.

Artificial Thallium Moult in Sheep

IT has been known in medicine since 1898 that thallium compounds taken internally will cause loss of the hair. This method has recently been used to produce moulting of the fleece in sheep, instead of shearing. Prof. N. A. Iljin (*J. Genet.*, **33**, No. 2) gives a short account of experiments in which the sheep's fleece becomes loose a few days after treatment and can be removed whole with the hands in a few minutes. Sheep with coarse and mixed wool have a natural annual moult which is absent from fine-woolled breeds such as the merino. Hybrids are found to exhibit segregation of this character of natural moulting. By thallium treatment, the moult may be induced in merinos and their naturally non-moulting hybrids. Extensive experiments with this method have been carried out on Soviet State Farms in the Crimea, Ukraine, Caucasus and the Moscow district, but as a considerable number of sheep were killed by an overdose during the experiments, it is evident that the effects of repeated doses on the animal will need to be known before the treatment can come into practical use.

Development of Crystal Analysis

SIR WILLIAM BRAGG, delivering the Sir Henry Trueman Wood lecture before the Royal Society of Arts on December 16, gave an account of the development of crystal analysis by X-rays during the last decade. The X-ray data may now be made to give a 'shadow picture' of the molecular structure which can be compared with chemical ideas of structural grouping. The dimensions of the structure can be determined with very considerable accuracy—the separation of atoms within about one per cent—and it is found that the characteristic separation of, say, carbon atoms persists in a number of related structures. Chemical ideas of valency, double and triple linkages, the benzene ring are all clarified by this method of study of the atomic separations. The investigation of structures is progressive in the sense that the information already gained can be used in the attack on more complicated structures. Important results have been obtained with proteins, and the properties of the protein chain explain the peculiarities of hair, muscle and similar biological structures. The X-ray diffraction patterns obtained from alloys show how a small quantity of an alloying element fits into the main lattice; while the progressive addition of alloy leads to the formation of new, characteristic lattices. The peculiar alloy structure called the γ-phase depends apparently on a fixed proportion (13:21) of atoms to valency electrons. X-rays, aided by electron diffraction, also give information about the crystal texture—the size and arrangement of the crystals as distinct from their inner structure; and the texture is the key to such different problems as the working of metals and the function of biological structures.

The Boulder Dam and its Equipment

IN *Engineering* for January 1 is a well-illustrated introduction to a series of articles which will deal with the mechanical, hydraulic and electrical features of Boulder Dam. These articles will be written by Mr. P. A. Kinzie, Mr. J. A. Winter and Mr. L. N. McClellan, who have each been responsible for some part of the equipment for the control and utilization of the water impounded by the Boulder Dam, which is not inappropriately described as "the greatest engineering effort of its kind in history". It was on December 21, 1928, that President Coolidge signed the Boulder Dam Act, which provided for the construction of a great dam on the Colorado River. The scheme had several objects. First, it was intended to prevent the serious floods which menaced the fertile district of the Imperial Valley; secondly, to conserve water for use in the same district during the hot dry summers; and thirdly, to provide a public water supply for the coastal cities of Southern California. The river has a length of approximately 1,700 miles, and drains an area slightly more than double the area of Great Britain. The site for the dam was chosen in Black Canyon about 300 miles upstream from the river mouth, a barren and inhospitable region, the character of which is well shown by the photographs in *Engineering*. The dam itself was completed in the summer of 1935. From the lowest portion of the foundation to roadway level it is 726 feet high; it is 660 feet thick at the base and 45 ft. thick at the crest, and contains about 6,600,000 tons of concrete. It is composed of massive vertical columns about 230 in number, interlocking both vertically and horizontally. Recently, the water impounded in the reservoir, Lake Mead, was estimated at ten billion gallons.

Electric Supply in Palestine

AN account of electric supply in Palestine since it was initiated in 1923, given in *Electrical Industries* of December 2, is of special interest in connexion with the political rioting which began last April. The pioneer of this supply was Mr. P. Rutenberg, who enlisted the support of the late Lord Melchett and the Baron E. de Rothschild. It was decided to have a national power supply from water-power, but as the rainfall for Palestine lasts only four months in the year, it was necessary to store the winter rainfall in reservoirs, the construction of which would take several years. It was advisable therefore to use temporary Diesel engine power stations at Haifa and Jaffa to begin the supply, whilst the Dagania dam across the River Jordan and the large one on the Tarmuck River were being constructed. In addition to these dams, Lake Tiberias, which forms a natural reservoir with a surface of 170 million square metres, was utilized. The water-power is converted into electrical power which by high-pressure electricity is distributed to Haifa and thence to the north and south of Palestine. In addition, a steam turbine power house was constructed in 1935 and a large power house called the 'Reading' (after the late Marquess of Reading) is being built in southern Palestine.

WHEN these plans are completed, the Holy Land will be as highly electrified as any territorial area in the British Empire. During the last three years, the consumption of electricity has quadrupled. There can be little doubt that industrialization is rapidly changing the character of Palestine and that electric power is the main factor in producing this change. Electric lighting, electric power driven machinery and all-mains wireless sets are to be found in small towns, villages and even in remote farming settlements. This is partly due to the fact that the immigrants who come from Germany, America, Czechoslovakia, Austria and the British Dominions, have been accustomed to the use of electric light in factory and home. It looks as if schemes for flooding the Dead Sea from the Mediterranean and so getting electric power possibly for sale to Egypt will soon be considered. One very beneficial effect would be that the constant evaporation from the greatly increased surface of water would humidify the atmosphere and so contribute to the fertility of the region.

Academic Freedom

THE report of the Conference on Academic Freedom at Oxford in August 1935 and the publication entitled "The Frustration of Science" form the text of a fine plea for academic freedom by M. J. Pelseneer in *Revue de l'Université de Bruxelles* of October–November. M. Pelseneer refers again to the various directions in which academic freedom is threatened and to the necessity for organized united resistance to those threats, and he emphasizes the way in which the freedom of the intellectual is linked up with the freedom of mankind. True liberty of thought is that which liberates mankind from the indignity of bondage. In particular, he pleads for tolerance in the matter of university appointments in the sense not merely of respecting the opinions of others but also in allowing them reasonable opportunity of expression. In this connexion it is interesting to note the conditions in the University of Heidelberg as set out on p. 98 of this issue of NATURE. M. Pelseneer, recognizing that human society must look to science for just laws and rational organization, even if their application to the distribution of production and government involves a social revolution, suggests that even within the limits of a given economic system, it is still worth while to discover the means of securing the minimum frustration of science.

Human Welfare and Human Efficiency

THE relation between industrial and social efficiency, discussed in a leading article in NATURE of October 3 dealing with Sir Josiah Stamp's address to the

British Association at Blackpool, has been further considered by Mr. W. H. Smyth in the *Berkeley Daily Gazette* of December 5. Mr. Smyth, protesting against the mechanical conception of efficiency, urges that ultimate human efficiency should imply the liberation of man rather than the efficient control of his actions, and that the former as it gains the creative interest of the worker is likely to be the best way of achieving, though indirectly, the latter. He suggests that an act of efficiency which deals with the human element incidentally but with products as its first consideration may inevitably involve disaster to the human element. The art of efficiency in fact is misdirected if it is concerned with production as an end in itself instead of with the development of men possessing vital initiative and creative powers. Mr. Smyth sees the issue as one between human worth and human productive efficiency and one that has a vital bearing on the evolution of alternatives to war. The very value which is now attached to the work of the National Institute of Industrial Psychology in reducing labour turnover, for example, lends powerful support to Mr. Smyth's other pleas that, even in industry, efficiency should be regarded in terms of human welfare as well as of mechanical output and processes.

Citizenship and the Universities

SHOULD training for citizenship be an integral part of every undergraduate's curriculum ? One of the smaller New England colleges, Hobart, announces a reorganization implying an affirmative answer to this question. Furthermore, the College hopes to make the bachelor's degree "represent less an aggregation of academic achievements and more an integration of intellect and of personality in the primary responsibilities of the citizen towards his community". The announcement is significant, according, as it does, with a growing tendency in the United States to emphasize the universities' obligation to the social order. In his inaugural address, published in *School and Society* of October 24, the president of the College explains that studies in economics, history, political science and social psychology will in future be so organized as to constitute a progressive four-year course culminating in its final year with a study of contemporary problems in American government and the means of social control. He points out that the 'orientation' courses commonly provided in colleges for the freshman year are well enough for opening the adolescent mind to a glimpse of the problems of the modern world, but are necessarily superficial and elementary compared with what is possible in the fourth year when the student has been equipped with a fairly comprehensive background of knowledge and is ready to envisage political and economic problems with interest as prospective factors in his own life. The dire need of the country for such stiffening as these reforms are calculated to provide is indicated by the statement that "Ballyhoo, the present and audible substitute for rational leadership, is well on the road to becoming the chief creator of American policy and politicians".

The National Botanic Garden of South Africa

KIRSTENBOSCH, part of the Groot Schuur Estate at Cape Town, South Africa, bequeathed to the nation by Cecil Rhodes, was set apart in 1913 for the purposes of a National Botanic Garden. The report of the Trustees for the year 1936 (issued August 1936) shows that, in spite of its small financial resources, a very gratifying amount of botanical, educational and economic work has been done. The objects of the Gardens are "the collection, cultivation and study of the indigenous flora of South Africa ; the preservation of the native vegetation of the areas under control ; and the introduction to cultivation in South Africa of selected economic plants, indigenous and exotic, and their preliminary trial". During the year under review, sixteen new species have been described, and many papers have been published. Large quantities of seeds of various species have been distributed to members of the South African Botanical Society and other institutions and the trade, and more than 200 lots of succulent plants have been propagated. Perhaps the Gardens' most useful activity is shown by the announcement that 1,108 lb. of *Barosma betulina* has been harvested, and also 102 lb. of *B. crenulata*, 1 oz. of Dalmatian insect powder flowers, 6 lb. of sumach, and 3 lb. of tansy—products which could be brought within the channels of commerce. Trials of lawn grasses are in progress, and many additions of fresh plants have been made to all parts of the garden. The report shows that the Gardens interpret every aspect of the flora of South Africa in a marked degree. Mr. F. W. Thorns has been appointed curator of the Garden, in succession to Mr. J. W. Mathews, who has held the post of curator since the foundation of the Garden in 1913.

British Empire Cancer Campaign

AT the sixty-first quarterly meeting of the Grand Council of the British Empire Cancer Campaign held at 12 Grosvenor Crescent on January 11, the following grants, in addition to those totalling £28,995 which were made at the annual general meeting in November, have been approved on the recommendation of the Scientific Advisory Committee of the Campaign : £200 to cover the cost of special physical investigations being carried out under the direction of Dr. F. G. Spear at the Strangeways Research Laboratory, Cambridge ; £500 for one year to Dr. H. J. Phelps, whilst carrying out experiments in connexion with Dr. Lumsden's anti-cancer serum under the supervision of Dr. Gye and Prof. McIntosh and £440 for one year to Miss C. F. Fischmann working in the Bernhard Baron Institute of Pathology at the London Hospital.

Tibet Earthquake of January 7

A GREAT earthquake was recorded in Great Britain at about 1.31 p.m. on January 7. At West Bromwich, as Mr. J. J. Shaw states, the needle of the seismograph was displaced by about 6½ in., or within half an inch of the amount produced by the Quetta earthquake of 1935. From the records obtained at Kew and Bombay observatories, it appears that the epicentre lay at distances of 4,700 and 1,850 miles from these stations. Thus, the earthquake must have occurred at 1.21 p.m., G.M.T., the epicentre being in eastern Tibet in about lat. 35° N., long. 97° E., a region about 500 miles north-east of the epicentres of the great earthquakes that occurred in southern Tibet on December 15, 1934, and January 3, 1935.

Announcements

THE Gold Medal of the Royal Astronomical Society has been awarded to Dr. Harold Jeffreys for his researches into the physics of the earth and other planets and for his contributions to the study of the origin and age of the solar system.

MR. D. L. EDWARDS has been appointed director of the Norman Lockyer Observatory at Salcombe Hill, in succession to the late Dr. W. J. S. Lockyer. Mr. Edwards joined the Observatory staff soon after the Great War, when the late Sir Norman Lockyer was in charge. The new assistant is Mr. D. R. Barber, of Exeter.

THE following appointments to the Colonial Service have recently been made: R. V. Burns, to be irrigation engineer, Ceylon; W. R. W. Ferguson, to be engineer, Water Supply Section, Geological Survey, Nigeria; F. W. Roe to be field geologist, Malaya; D. F. Stewart (inspector of plants and produce, Gold Coast), to be agricultural officer, Uganda; H. D. Tonking (assistant bacteriologist, Kenya), to be senior pathologist, Mauritius.

AT the invitation of the Royal Society, the International Council of Scientific Unions will hold its triennial General Assembly at Burlington House, London, on April 27–May 4. China, through the Academica Sinica of Nanking, has recently joined the Council, which now includes forty-two countries in addition to the International Unions of Astronomy, Geodesy and Geophysics, Chemistry, Scientific Radio, Physics, Geography and the Biological Sciences.

PROF. WALTER B. CANNON, George Higginson professor of physiology in the Harvard University Medical School, has been elected a corresponding member of the National Academy of Medicine of Buenos Aires.

PROF. WILTON MARION KROGMAN, associate professor of anthropology at the School of Medicine of the Western Reserve University, Cleveland, has been awarded the one thousand dollar prize of the *Readers Digest* for his article entitled "The Skeleton Speaks", in which he gave an account of some of his medico-legal interpretations of crime.

THE German Rontgen Society has nominated as honorary members Prof. Aristide Busi, director of the Radiological Institute of the University of Rome, and Prof. Arthur C. Christie, professor of clinical radiology, Gaytown University Medical School, Washington, D.C., and as corresponding members Dr. B. K. Kirklin of the Mayo Clinic, Rochester, U.S.A., and Dr. Emil Lazeanu, president of the Rumanian Radiological Society.

DR. LAWRENCE WADE BASS has recently been appointed assistant director of the Mellon Institute of Industrial Research. Dr. Bass, who previously distinguished himself by his researches in organic chemistry and biochemistry, has been devoting special attention to industrial research management and chemical economics. He has made many important contributions to chemical literature. He and Dr. P. A. Levene of the Rockefeller Institute published in 1931 a comprehensive treatise on "Nucleic Acids" as a monograph of the American Chemical Society. Dr. Bass and Dr. Levene have also written chapters for the "Biochemisches Handlexikon", a standard German reference work.

THE Institute for Science of Labour in Japan has removed from Kurashiki to Tokyo and will be reconstructed with the aid of the Imperial Government and of the Foundation for the Promotion of Scientific and Industrial Research of Japan. The director is G. Teruoka and the new address, Institute for Science of Labour, Aoyama 5 Chome, Tokyo, Japan.

A SCHOOL of criminological science attached to the faculty of law has recently been opened at the University of Brussels.

DR. OTTO GESNER has been nominated professor and director of the Institute of Pharmacology in the University of Halle.

PROF. PIETRUSKY has resigned his office of rector of the University of Bonn and has been succeeded by his nominee, Dr. Karl Schmidt, professor of ophthalmology at Bonn.

A NUMBER of reprints of many of the scientific papers of the late Prof. T. M. Lowry are still available, and may be had on application to Dr. C. B. Allsopp, The University Chemical Laboratory, Cambridge. Postage should be enclosed with each request.

H.M. STATIONERY OFFICE has undertaken the agency for the natural history publications of the British Museum (Natural History), South Kensington, S.W.7. Many of these are scientific monographs of the greatest value to students of the various branches of nature-study represented in the Museum. The economic series are of a more popular interest. A wide range of popular postcards is also on sale. These illustrate the various animals, birds and birds' eggs, butterflies, moths, bees, wasps, beetles, plants, etc., which can be studied in detail at the Museum itself. Inquiries relating to the Museum's publications may be addressed to any of the sale offices of H.M. Stationery Office.

ERRATUM.—In the article "Chemistry of Essential Oils" in NATURE of January 9, p. 80, par. 1, line 6, for "Australia" read "eastern coast of Australia".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 117.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Maturity and Fecundity of One-Year-Old English Native Oysters, *O. edulis*

BY the courtesy of Major A. Gardner, one of us (J. H. O.) was able to study the spawning, spatfall and growth of the native oyster, *O. edulis*, on the Blackwater and Roach oyster beds in 1935 and 1936. The summer of 1935 resembled that of 1921 in being continuously warm, and also in yielding heavy falls of spat on the Blackwater. In 1922, one of a small sample of one-year old oysters obtained there experimentally was found at this extremely early age carrying larvæ[1]. The prevalent notion is that English natives do not mature until they are three years old. In a lot of 104 selected well-grown 1935 spat from the Blackwater kindly supplied by Major Gardner on August 6, 1936, two were found with young, three were mature or nearly mature females and fourteen were ripe males. New evidence was therefore obtained of the possibility of English native oysters maturing as females and producing young at an age of a little more or less than one year after an exceptionally warm season.

There is virtual certainty that all the sample were 1935 spat although obtained from the beds, as (1) the 1934 spatfall was a failure so that mixture of 1934 spat is improbable; (2) the growth of the 1935 spat has been followed closely, rendering their identification practically certain; (3) the average weight of a hundred of the dried shells is 4·83 gm. and that of the spawning and ripe females respectively 5·8, 6·2, 3·9, 5·4 and 4·6 gm.; the average length and breadth of 104 shells is 42·6 mm. by 41·4 mm. and that of the females 43 mm. by 43 mm. The females have only slightly heavier shells on the average than the selected sample (see Fig. 1).

It is not possible to discuss here all the problems arising out of early female maturity, but it may be noted that the actual percentage of mature females at this early age was small in 1936; on the River Roach only one mature female occurred among 276 of the largest obtainable in August and September.

We estimated the number of shelled and just coloured larvæ borne by one of the two individuals with young and found approximately 240,000. By the same method of estimation, the larvæ obtained from the smaller one-year old oyster in 1922 were found to number at least 84,000. Dantan[2] found in six French one-year old *O. edulis* 69,000–144,000 and an average of about 95,000. In estimating the number of larvæ it was found that haphazard stirring in a concave bottomed bell-jar was not entirely satisfactory. Concordant results were obtained by using an almost flat-bottomed wide cylindrical glass jar (15 cm. in diameter) and a special stirrer of perforated zinc in the form of a cross with a hole in the centre, and at the opposite ends of one arm upturned limbs to allow the stirrer to be moved up and down while samples were actually being taken.

Successive samples taken in this way with a 2·5 c.c. Stempel pipette from 2,000 c.c. of suspension liquid containing the 1936 batch of young yielded 298 and 295 larvæ at the surface, 274, 277 and 287 in mid-water and 305, 313, 328 and 311 at the bottom; the last figure in each group referring to side samples and the others to central samples. 5,000 larvæ had previously been taken from the sample. As a check on the method, these 5,000 larvæ were transferred to 1,000 c.c. of 5 per cent formalin, and 2·5 c.c. samples taken as before with the Stempel pipette after and during stirring. The numbers obtained were respectively 13, 13, 11, 13 central surface, 22, 12, 14, 10 middle middle, and 15, 11, 14 central bottom. With uniform distribution 12 or 13 larvæ would be taken in such samples. In all these samplings with the exception of one, the 22 in the last lot, the variation from the mean is less than the square root of the mean. The mean gives therefore a good approximation; and the method of sampling is satisfactory. It is interesting that the high figure 22 was the first sample taken from the known number of 5,000 after a long period of settlement, indicating interlocking or inefficient mixing, and that it is advisable to omit sampling after the first mixing to ensure even distribution.

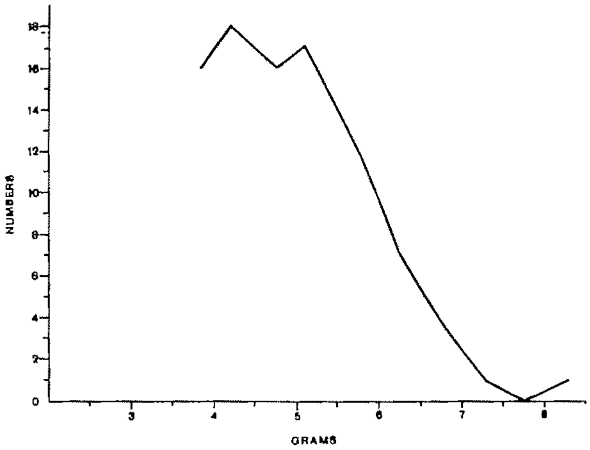

Fig. 1.

OPTIMAL GROWTH IN NATURAL ONE-YEAR OLD ENGLISH NATIVE OYSTERS, *O. edulis*; R. BLACKWATER, JULY 1936–AUGUST 1936; 92 SELECTED LARGEST SHELLS. (MEAN DRY SHELL-WEIGHT IN HALF-GRAM GROUPS IS GIVEN AFTER DRYING AT ABOUT 80° C. FOR ONE HOUR.)

The volume of the larvæ after one and three days settlement was found to be approximately 0·575 c.c., giving about 417,000 per c.c. after considerable shrinkage in 5 per cent formalin during four months. This result is considered not incompatible with an independent count of 11,928 larvæ (preserved in the slightly smaller trochosphere stage) in one drop of liquid, giving about 300,000 per c.c. without close packing.

Interchange of Hydrogen Isotopes in Complex Cobaltammines

ERLENMEYER and Gartner[1] have reported that interchange of hydrogen isotopes takes place when hexammine cobaltic nitrate, $[Co(NH_3)_6](NO_3)_3$, is dissolved in heavy water, all the hydrogen atoms being replaceable. Bankowski[2], however, has stated that the hydrogen in complex ammines is only partially replaceable, one atom being interchanged in $[Co(NH_3)_4(H_2O)_2]Cl_3$, and three atoms in $[Co(NH_3)_4CO_3]Cl$.

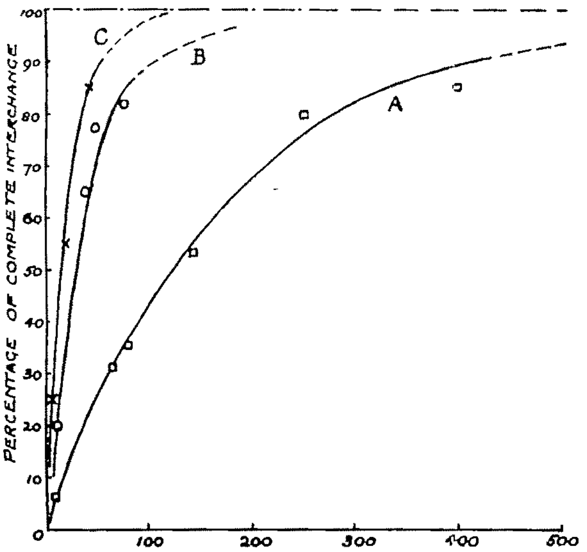

Fig. 1.

We have re-examined the question of isotope interchange with complex ammines in solution, with special reference to 1,6 dinitro tetrammine cobaltic nitrate, carbonato tetrammine cobaltic nitrate, hexammine cobaltic chloride and triethylene diamine cobaltic chloride. In agreement with Erlenmeyer's results, we find that all the amine hydrogen contained in the complex may be interchanged with deuterium; we also find, however, that at 25° and 35° the interchange proceeds quite slowly, the time of half change being several hours; and Bankowski's inherently improbable conclusion may be due to his failure to observe this fact.

In our experiments, which have been most fully worked out for hexammine cobaltic chloride, the salt was dissolved in approximately 3 per cent heavy water, and at suitable intervals a portion of the solution was removed and the extent of interchange was ascertained by separating the water therefrom and observing its density relative to that of the original heavy water by a micro-flotation method, giving relative densities within ± 0·5 γd on a sample of 0·25 c.c., which will be described elsewhere. The first experiments were made by distilling off the water from the samples *in vacuo* as rapidly as possible (Fig. 1, *A* and *B*). Afterwards, it was found to be preferable to add the samples to excess of dry, powdered, mercuric chloride, thus precipitating the complex cation as the mercurichloride, $[Co(NH_3)_6]Cl_3.HgCl_2$, and arresting the interchange quite sharply. After filtration, the water was purified by distillation and its density was determined as before (Fig. 1, *C*).

As may be seen from Fig. 1, complete interchange requires a considerable time, and the interchanges at shorter times lie on curves asymptotic to the line representing complete interchange.

By a further modification of the experimental method, it has been possible to make a full kinetic analysis of the reaction mechanism, and the results of this further work, which appear to be of considerable significance in relation to the theory of the co-ordination complex, will shortly be published in full.

The Fifth Skull of Peking Man

A RECENT letter via the trans-Siberian mail brings the information that the fifth skull of Peking man, lately discovered, is the most complete specimen ever found at Choukoutien, near Peking.

It was discovered by Mr. L. P. Chia on November 26, 1936, in the same layer of the fossiliferous deposit as the other two skulls collected ten days before (see NATURE, Dec. 12, 1936, p. 1004, and Dec. 19, 1936, p. 1056), but about six metres farther south.

Except for the teeth, which are missing, this specimen is exceptionally well preserved and complete; the nasal bones and the left orbit are undamaged, and connected with the back parts, including the foramen magnum and other delicate bones, which are in very good condition. The middle vault of the skull has not been badly crushed in the brecciated matrix, which has made it possible for Prof. F. Weidenreich to remount it within a week of its transport from the field to the laboratory.

This skull (male type) does not belong to a fully adult individual, but to one who is evidently older than that represented by the No. 1 skull. The orbital ridges are more strongly developed than, but the general architecture remains the same as, the skull No. 1, described by the late Prof. Davidson Black.

Prof. Weidenreich is now preparing a short note which will appear in the near future, and will present his preliminary observations, with diagrams, on the last three skulls. Before the appearance of his official statement, I hope that scientific workers will withhold their judgment on the latest discoveries of *Sinanthropus*, and ignore the inaccurate rumours already circulated that the last three skulls of *Sinanthropus* are identical with the *Pithecanthropus* or *Homo neanderthalensis* skulls.

A Simple Means of Checking the Michelson-Morley Experiment

THE epoch-making work of Prof. Dayton C. Miller, as reported two years ago in NATURE[1], has established that the small effect found by Michelson and Morley is a reality. In a paper read by me before the American Physical Society which has as yet only appeared in abstract form[2], it is shown that there is a v^2/c^2 effect in both arms of the interferometer (also shown by Voigt[3] in 1887). If, however, the ray of light is not perfectly normal to the end mirror, the ray is displaced during the motion and this displacement gives rise to a small effect (about one four-thousandth of v^2/c^2 in Miller's case—due to the ray having an angle of obliquity of about 1′). I find on applying my formula to his results, a value for the cosmic motion of 300 km./sec., while his method of computing the effect gives 200 km./sec. The discrepancy between these results was traced to his floating apparatus being unbalanced, causing the interferometer to be *very slightly* out of level. Secondary effects due to this slight unbalance may be seen in his results, as well as the effect due to the obliquity of the ray, and it has been found, by inclining one arm of the interferometer while the other remains level, that a very large displacement of the fringes may be produced, since it is the *component* of the cosmic velocity in each arm which affects the ray in that arm.

As shown by Miller, the cosmic velocity is nearly vertical at some time during the day, and at some other time nearly horizontal. Therefore twice a day the cosmic velocity makes an angle of 45° with the normal to the plane of the horizon, and by inclining one arm of the interferometer at 45° while the other arm remains level, rotation about a vertical axis will bring the 45° arm into the line of direction of the cosmic motion, and we shall have in this arm not merely a component of this velocity, but the full value of 300 km./sec. When rotated 180° from this position, the 45° arm will be at right angles to the cosmic motion and the component will have a zero value, and we therefore have a full shift of the fringes between two points 180° apart. In the level arm there will be no change because, as shown by Voigt, while the motion of the source gives us a v/c effect and a v^2/c^2 effect, the v/c effect is annulled by the motion of the observer, the v^2/c^2 effect remains and is independent of the orientation of the interferometer, the wave surfaces being spherical. (See page 50 of Voigt's Doppler effect paper[4].)

It would be rather difficult to incline a large interferometer like Miller's at 45°, but it can easily be done with a small one. A simple turntable may be used which may be tested for suitability by placing a level interferometer upon it, and noticing whether there is any appreciable fringe shift on rotation; if not it may be assumed that the turntable is satisfactory. A good carpenter can make a framework in two or three hours that will support the interferometer solidly and stably at the proper angle. Send the ray of light from the source along the horizontal arm, and the fringes from the 45° arm may be seen by means of an auxiliary plane mirror suitably mounted (an ordinary mirror will do), and after having properly adjusted the interferometer, a short focus horizontal telescope may be used to view the fringes reflected from the auxiliary mirror.

Preliminary measurements with an interferometer having equal arms 6¼ in. long gave a shift of approximately six tenths of a fringe, in agreement with the following calculations.

$$\delta F = \frac{2l}{\lambda}\cdot\frac{v^2}{c^2} = \frac{31\cdot75}{5\cdot461 \times 10^{-5}}\cdot\frac{9 \times 10^4}{9 \times 10^{10}} = 0\cdot581.$$

Contrary to expectation, the magnitude of the fringe shift seems to be practically the same at any time of day.

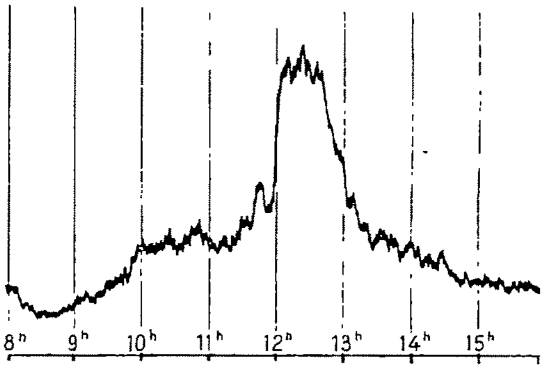
Abnormalities of the Ionosphere and Bright Solar Eruptions

IN a letter published in NATURE of December 12, 1936, p. 1017, Mr. H. W. Newton states that in December a bright hydrogen eruption was observed at the Royal Observatory, Greenwich (beginning at 11h. 57m. U.T. and bright eruption at 12h. 03m.) and he directs attention to the fact that this eruption coincided with "a marked abnormality in the ionosphere".



St. Cyr, 27 kc./s. December 3, 1936.

Fig. 1.

On the same day and at the same time, I pointed out in Paris (St. Cyr) a large increase in the number of atmospherics on 27 kc./s. (11,500 m.). Fig. 1 is from a photograph of the interesting part of the St. Cyr record. African records (Tunis and Rabat) show the same phenomenon at the same time, but less intense. These sudden rises in the number of atmospherics are not new phenomena. I have already reported such increases, some even more sudden, and I have pointed out that they depend on modifications of the ionosphere[1].

The increase of the number of atmospherics received does not correspond with the number of atmospherics produced but with an improvement in the propagation of the long waves over a great distance.

The same ionospheric phenomenon is obvious as an opposite effect in the short-wave spectrum. M. Jouaux, secretary of the Comité Français de Radiotélégraphie scientifique, was the first to emphasize the interest[2] of the study of sudden fading in short-wave commercial traffic; they have since been observed on different continents. They coincide with the increase of atmospherics on long waves[3].

The study of atmospherics has now acquired a new interest. It seems certain that some peculiarities of these records are closely associated, in time, with ionospheric perturbations, which, at least in part, are the direct consequence of solar eruptions.

Equivalent Particle-Observers

IN a letter to NATURE, Prof. Synge has pointed out[1] that the condition of equivalence of two distant particle-observers does not completely define the time-scale of either, and that *any* two distant particle-observers may be provided with clocks which satisfy the condition of equivalence and make the relative velocity of the two equal to zero. Synge concludes that the relativistic theories developed by Milne and by me fail to dispense with both the concept of rigid bodies and the concept of absolute clocks.

My approach to the relativistic kinematics differs from Milne's in that he employs the concept of equivalence to establish reference systems consisting of dense aggregates of synchronous particle-observers relatively at rest. Now Synge's analysis of the time-scales of two equivalent particle-observers whose world-lines do not intersect shows that all successive time intervals $F_{n+2,\,n+3} - F_{n,\,n+1} = 2k$ (Synge's notation) must be the same if the observers have no relative velocity. As k is the distance r between the particle-observers divided by the velocity c of light, this means that the time-scale of either observer is divided uniquely into successive intervals of magnitude $2r/c$, but that the subdivision of any one of these intervals into smaller intervals is arbitrary. As the distance r between the two observers is made smaller, however, the smallest interval $2r/c$ uniquely determined becomes proportionately smaller. Hence, even the smallest time intervals on the clocks of a dense assemblage of synchronous particle-observers constituting a reference system are completely determined.

Now consider two particle-observers P' and P'' whose world-lines cross, but neither of which intersects the world-line of P. As Synge indicates, with one pair of clocks we can make P and P' synchronous and relatively at rest, whereas with another pair we can make P and P'' synchronous and relatively at rest. Therefore we can associate with a single particle-observer P more than one *linear* reference system. This arbitrariness, however, disappears in the three-dimensional case, where we impose a geometry on a reference system. For the papers of Engstrom and Zorn[2] and of Robertson[3] show that we can associate at most a single Euclidean reference system with P. Hence it would seem that we are able to dispense with both the concept of the rigid measuring rod and that of the isochronous clock in this case, or, to put the matter the other way around, we have established an ideal criterion by which to test both the rigidity of material rods and the isochronism of material clocks.

The statement in my paper[4] which Synge criticizes should be taken to refer to the *relative* readings of the clocks of P and P'.

Microscopic Examination of Fog-, Cloud- and Rain-Droplets

OF the many methods proposed hitherto for the measurement of the size and concentration of droplets in fogs and clouds, none can be considered as quite satisfactory. The extensively used method of diffraction rings (corona) can be applied only in the relatively rare case of isodisperse fogs. The photographic method devised by Findeisen[1] is rather complicated, and can scarcely be used in field work. The direct measurement of the droplets collected on greased wires or on glass slides is hampered by very rapid evaporation of the droplets and distortion of their spherical shape. The method proposed recently by Hagemann[2], namely, collecting the droplets on a thin layer of castor oil and photographing them during their fall through the layer, has many disadvantages and can be used only for droplets with a radius less than 5 μ.

After having tried unsuccessfully many different methods, we discovered that quite satisfactory results can be obtained by collecting the droplets on glass slides coated with a freshly melted mixture of vaseline and light mineral oil. The proportion of the ingredients depends on the temperature of the air (about 1 : 3 at 20° C., 1 : 5 at 0° C., and so on).

This mixture has the property of instantly enveloping the water droplets as they settle with a thin film, which practically prevents both evaporation of the droplets and condensation of vapour on them, without affecting their spherical shape. The droplets thus collected on the slides can be preserved in a damp atmosphere for many hours without showing any perceptible diminution in size. The only condition which has to be observed is that the temperature at which the droplets are kept and measured is equal to or below that at which they were collected or, at any rate, does not exceed it by more than a few degrees. The smallest droplets, distinguishable only with a microscope objective of the highest resolving power, can be examined in this way, as well as rain-droplets of 2–3 mm. diameter. The thickness of the vaseline layer must, however, be greater than the diameter of the droplets.

Fig. 1 (left hand) shows a photomicrograph (magnification 1 : 50) of droplets collected during a 10-minute exposure of glass slides in a dense fog, which occurred in Moscow on the night of November 2 (air temperature, 5° C.). The size of the droplets lay within the limits of about 0·006–0·030 mm. radius. In order to determine the real distribution of the sizes of droplets, the glass slides would have to be put at the bottom of a chamber filled with the fog. All the droplets contained in the chamber should then be allowed to settle on the bottom. This could not be done, as fogs are very rare in Moscow and this one happened quite unexpectedly. Fig. 1 (right hand) shows a photomicrograph taken of rain droplets (magnification 1 : 10).

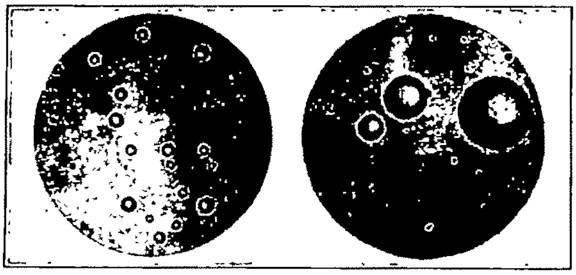

Fig. 1

FOG PARTICLES (LEFT), × 50; AND RAIN DROPLETS (RIGHT), × 10

All the apparatus needed for the visual or photomicrographic measurements of droplets (an electric battery for illumination included) weighs about 12 lb. and the method can be readily used in the field, during balloon flights, etc. Measurements made from a balloon continuously kept in equilibrium with the surrounding air would give invaluable information about the kinetics of the formation and precipitation of clouds—processes about which very little is as yet known.

Preparation of a Highly Active Alcohol Apo-dehydrogenase from Yeast

IT is generally recognized that an active dehydrogenase system consists of three principal components: (1) an apo-dehydrogenase, the non-dializable and thermo-labile colloidal carrier, protein in nature; (2) a co-enzyme, crystalloidal and comparatively thermostable; and (3) a flavo-protein, capable of reversible oxidations and reductions. Euler and others have advanced the view that the specificity of dehydrogenases is intimately associated with the specific protein or proteins constituting the apo-dehydrogenase, the isolation of which in a state of integral purity and high activity is necessary for an elucidation of the groups responsible for the enzymic activity. With this end in view, we have commenced a study of the isolation and purification of the alcohol apo-dehydrogenase from bottom yeast.

Dried yeast (one part), macerated with toluenated water (3 parts) at 30° C. for three hours, yields an extract which contains about 70–75 per cent of the apo-dehydrogenase, and this extract has been used as the starting material for the isolation and purification of the active protein. The activity or the concentration of the apo-dehydrogenase is expressed as seconds per milligram of protein nitrogen, required to decolourize 0·2 c.c. of a standard solution of methylene blue (1 in 5,000), in presence of an excess of the other components of the dehydrogenase system, the substrate, the cozymase and the flavo-protein. Measured on this standard, the crude extract has an activity which corresponds to 808 seconds per milligram of protein nitrogen.

The maceration extract, when treated with ammonium sulphate to full saturation, yields a precipitate centrifugible with difficulty which, however, easily dissolves in water giving a clear yellow solution.

When this solution is progressively saturated with ammonium sulphate, two distinct precipitates are obtained, one at half saturation and the other at full saturation. These precipitates, *A* and *B*, have activities respectively corresponding to 46 and 81 seconds per milligram of protein nitrogen, showing thereby that a purer preparation of the apo-dehydrogenase is obtained at half saturation. Preparation *B*, however, has been found to be comparatively free from the flavo-protein, as measured by its high response to the addition of the flavine enzyme.

Further purification of the preparation *A* is accomplished by re-dissolving the wet precipitate in water and carrying out an adsorption with zirconium hydroxide at *p*H 5. The active protein can be eluted from the adsorbate by Sørensen's *M*/15 phosphate buffer, *p*H 6·8, and a further purification can be effected by repeating the adsorption and elution under the same conditions. By adopting this procedure, it has been possible to obtain a preparation possessing an activity of 6 seconds per milligram of protein nitrogen and representing a 135-fold purification.

Experimental Induction of Ovulation with Progesterone

THE injection of pregnancy urine extract or of anterior pituitary extract causes ovulation in *Xenopus lævis*, the South African clawed frog. Ovulation is accompanied by swelling and hyperæmia of the anal labia. In an attempt to analyse the hormonal control of the labial reaction, œstradiol (Progynon B oleosum forte) and progesterone (Proluton) were injected separately and together into a number of female frogs. Injection of both hormones together elicited the full labial reaction and in addition induced ovulation. Ovulation occurred on injection of progesterone alone but not with œstradiol alone. Progesterone also caused ovulation in hypophysectomized animals. Ovulation had previously been obtained only with pregnancy urine and anterior pituitary extracts. The results of this preliminary investigation were communicated to the Royal Society of South Africa in October, 1936. The following is an account of a more extensive investigation undertaken since then.

Large numbers of frogs were hypophysectomized. In some the whole pituitary (anterior and posterior lobes) was removed, in others the anterior lobe alone was removed. Ten days after the operation, progesterone in doses of 0·1 mgm. and 1·0 mgm. was injected into normal animals and into the two types of hypophysectomized animals. Twenty hours after injection, readings were taken (*a*) of the percentage positive response and (*b*) of the extent of ovulation in positive animals. The latter was placed on a quantitative basis by assigning arbitrary symbols to the degree of ovulation: 1 or 2 according to the number of eggs in the oviduct; 3 or 4 according to the number in the pars uteri; and 5 or 6 according to the number of eggs extruded from the cloaca into the water in the container. The total score of all positive animals divided by the number of positive animals gives a figure which has been called the ovulation index. When less than 10 per cent of animals ovulate, not much significance can be attached to the index. The maximum ovulation index is 6.

Immature normal animals (15–20 gm.) were also injected with progesterone. The average weight of the mature animals was 39 gm.

Type of animal	0·1 mgm. Progesterone		1·0 mgm. Progesterone	
	Percentage response	Ovulation index	Percentage response	Ovulation index
Normal	35	2·3	100	4·5
Anterior lobe removed	16	1·2	67	2·8
Both lobes removed	6·5	(1·5)	30	3·1
Immature normal	9·5	(2·0)	43	3·0

The results show that ovulation occurs in the absence of the pituitary, but that both the anterior and posterior lobes must be present before the maximum percentage of positive response can be obtained. On the other hand, an increase in the extent of ovulation is dependent upon some factor in the anterior lobe alone. Immature animals give a higher percentage response than completely hypophysectomized frogs but the same ovulation index.

Normal and completely hypophysectomized animals were injected with pregnancy urine extract. The dose chosen was that which just gave 100 per cent response when injected into normal animals. The hypophysectomized frogs gave 100 per cent response and an ovulation index of 5·5. The index in normal frogs was 5·0.

There was no significant difference in percentage response and ovulation index between completely hypophysectomized animals injected with progesterone alone and the same type of animal injected with progesterone and Parke, Davis pituitrin.

The ovulating effect of progesterone is strikingly demonstrated by its action on the excised ovaries of normal and hypophysectomized animals. The ovary is excised and placed in a glass dish containing Ringer's solution. The addition of 1 mgm. progesterone causes extrusion of numerous ova within 8–10 hours at a temperature of 21° C.

Coupling, ovulation and fertilization of eggs were induced by injecting males with anterior pituitary extract and females with progesterone. Ovulation and oviposition occur after injection of so small a dose as 0·05 mgm. progesterone.

Since the completion of these experiments, Shapiro[1], at the National Institute for Medical Research, Hampstead, has confirmed the findings for progesterone induced ovulation in *Xenopus* and has obtained the same result with the following steroids: methyltestosterone, testosterone, *allo*-pregnanedione, androstenedione, *trans*-dehydroandrosterone, *cis*-androstanediol, androsterone, Reichstein's adrenal substance J, "Eucortone" adrenal cortical extract.

Segmental Interchange Lines in *Pisum sativum*

IN collaboration with Miss Pellew, crosses between a number of lines of spontaneous or natural origin, showing interchange of segments between non-homologous chromosomes in *Pisum sativum*, have been studied at the John Innes Horticultural Institution, Merton, and at the Botanical Department, University of Manchester.

As a result of the analysis of the chromosome associations at meiosis in these crosses (seven pairs or an association of four—not a ring—results when the same two chromosomes are concerned in the two interchanges, an association of six when one chromosome is common to both interchanges, and two rings of four when entirely different chromosomes are affected), seven types differing in chromosome structure and therefore called 'structural types' have been distinguished, and their interrelationships determined. The chromosomes taking part in these interchanges are as follows, where arbitrary numbers are given to the seven haploid chromosomes of the normal or standard type:

Structural type 1	The normal or standard type. Chromosomes 1, 2, 3, 4, 5, 6, 7.
Structural type 2.	Hammarlund's *K*-line. Chromosomes 1 and 2 interchanged.
Structural type 3	The Thibet interchanged line. Chromosomes 1 and 3 interchanged
Structural type 4.	Extra rapid. Chromosomes 3 and 5 interchanged.
Structural type 5.	An interchanged type from Miss de Winton's material Chromosomes 4 and 5 interchanged.
Structural type 6	Wing's line. Chromosomes 1 and 4 interchanged.
Structural type 7.	The doubly-interchanged type from structural type 2 × structural type 3. Chromosome 1 interchanged with 2 and 3

Structural type 7 when crossed with structural type 6 gives, as expected, an association of eight chromosomes at meiosis, the highest association yet reported in *Pisum*.

Nilsson[1] studied the relationships between structural type 4 and three other types which cannot be classified in relation to those recorded in the present communication until the necessary tests have been made.

Linkage in Structural Hybrids in *Pisum sativum*

THE genetical analysis of some of the interchanged lines in *Pisum sativum*, reported on by Mrs. Sansome above, has given evidence on the distribution of the genes in the normal structural type. In plants of normal structure the genes *R* (R/r = round/wrinkled cotyledons) and *A* (A/a = coloured/white flowers) have been exhaustively studied in F_2 families from self-fertilization. By this method no clear indication of linkage was found. From back-crosses (453 plants from heterozygous females, and 418 plants from heterozygous males) 47 per cent of crossing-over was obtained[1]. Hence, in a recent summary of our knowledge of linkage in *Pisum*, these two genes are placed in different chromosomes[2].

Chromosome 1 of the normal structural type has undergone interchange with three other chromosomes in types 2, 3 and 6. When these three types are crossed with the normal, and the F_1 structural hybrids are also heterozygous for R and A, the F_2 progenies show either linkage between R and A, with about 30 per cent crossing-over (in hybrids 1 × 2 and 1 × 6), or linkage of both genes with the gametic sterility by which the position of the translocation is indicated (in hybrid 1 × 3). The evidence is derived, in hybrid 1 × 2, from back-cross ratios, and in hybrids 1 × 3 and 1 × 6[3] from F_2 ratios. Hence it follows that the genes R and A lie in the one chromosome of the normal type common to all three associations of chromosomes in the hybrids at meiosis, that is, in No. 1 of Mrs. Sansome's list.

That linkage may be shown in structural hybrids but not in homozygous types may be expected from the slight reduction in chiasma frequency observed by Sansome[4] and Sutton[5] and characteristic of such hybrids. Further, the incidence of gametic sterility in relation to other genes serves as a new locus. Hence the genetical analysis of structural hybrids may be a more effective method of studying the distribution of the genes than the analysis of structurally homozygous types.

Technique of the Painting Process in the Cave Temple at Sittannavasal

As an extension of my studies[1] on Indian paintings, I have had recently an opportunity of investigating the technique of the painting process adopted in the cave temple at Sittannavasal in the Pudukottah State, South India, situated at a distance of about 42 miles by road from Tanjore. This cave temple is very small, being about 24 feet long, 12 feet wide and 11 feet high. The interior was at one time fully painted, but at present the paintings are visible only on the ceilings, the capitals and the upper parts of the pillars. These paintings, which can be assigned to the time of the great Pallava king, Mahendravarman I (c. 600–625 A.D.)[2], represent the best specimens of Jain mural paintings of the classical or Ajanta school extant in India, and there can be no doubt about their æsthetic merit or high importance from the point of view of history.

From a study of the painted stucco, it is clear that the technique adopted in the execution of these paintings is one of *fresco-secco* or painting in lime medium on plaster. The stucco is composed of the *Rinzaffo* or rough coat of lime plaster with a fine lime wash thereon. The lime wash was probably given while the plaster was still wet. The thickness of the stucco depends on the nature of the surface of the wall and the ceilings, and varies from 1·9 mm. to 3·4 mm. and in certain places it goes up to about 8·9 mm.

The results of analysis of the stucco (excluding the lime-wash) were as follows:

	Per cent
Moisture	2·14
Silica, SiO_2	48·91
Iron and alumina, $Fe_2O_3 + Al_2O_3$	3·98
Carbon Dioxide, CO_2	18·07
Lime, CaO	24·37
Magnesia, MgO	0·35
Sulphuric anhydride, SO_3	0·11
Loss on ignition	0·65
Undetermined (mostly alkalis)	1·39
	99·97

The only inert material used with the lime is sand.

So far as pigments are concerned, lime has been used for the white, carbon for black, yellow and red ochres for yellow and red, lapis lazuli or ultramarine for blue, terre verte for green and a mixture of the last two for bluish-green.

Full details of the investigation will be published in the Technical Studies of the Fogg Art Museum of Harvard University.

Raman Spectrum of Benzene Vapour

MUCH interest is attached to the structure of benzene, and a series of important papers[1] dealing with this subject and based mainly on Raman, infra-red and emission spectra have recently appeared from University College, London. In this connexion it is very desirable to possess a knowledge of the Raman spectrum of benzene vapour, but no data are yet available. Fig. 1 (upper spectrum) shows the Raman spectrum of benzene vapour obtained by us at a pressure of 15 atm. and a temperature of 200° C.; the lower spectrum is the Raman spectrum of the liquid taken alongside, keeping the conditions regarding slit width, etc., unaltered but reducing the time of exposure. Fig. 2, *a* and *b*, are photometric records of the wings accompanying the λ 4077 and λ 4046 lines respectively in the vapour. Fig. 2, *c*, is the record of the wing accompanying the line λ 4046 in the liquid taken under identical conditions. Among other notable features, the following changes which take place as we pass from the liquid to the vapour are of special significance.

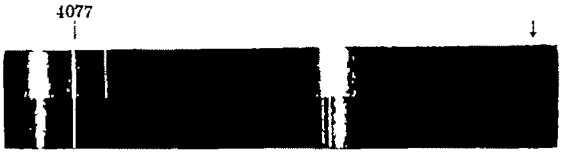

Fig. 1

RAMAN SPECTRUM OF BENZENE VAPOUR (ABOVE), LIQUID (BELOW).

The principal Raman line 992 shows no shift. 3061 shows a definite shift (see arrow in Fig 1) and has a value of 3069 in the vapour. 3047 has either completely disappeared or has been considerably weakened. The rotation wings accompanying the Rayleigh lines, which show no intensity maximum separated from the centre (Fig. 2, *c*) in the liquid, develop a distinct maximum at the expected position (Fig. 2, *a* and *b*) in the vapour. The absolute intensity of the rotation wing, as judged by comparing it with the 992 Raman line, increases enormously as we pass into the vapour state. For example, the wing accompanying the 4077 line has not been recorded at all in the liquid whereas it is quite intense in the gas (see Fig. 1), in spite of the fact that the 992 Raman line is recorded with greater intensity in the former than in the latter.

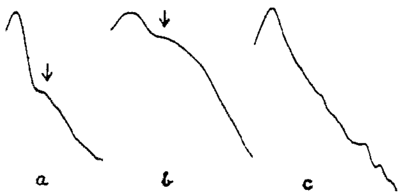

Fig. 2.

The significance of these and other features of the investigation will be discussed by us in detail elsewhere.

Active Nitrogen

IN their recent paper on the afterglow in active nitrogen, Cario and Stille[1] have doubted the reality of the production in the nitrogen afterglow of the N_2^+ first-negative bands and those bands of the N_2 first-positive system which originate on vibrational levels higher than $v' = 14$. It is suggested that my results were due to an accidental superposition of light from the exciting discharge on that of the afterglow.

An examination of the afterglow photographs published by Cario and Stille shows immediately the reasons for their failure to observe the above mentioned bands in the afterglow. Their nitrogen was not purified enough for the tube to reach what I have called the auroral stage. Their photographs show the bands due to nitric oxide and cyanogen in the spectrum of the afterglow, whereas these bands, as an examination of my published spectra will show, should have completely disappeared before the auroral stage is reached.

During the preparation of more than a score of tubes, I have passed through the stage photographed by Cario and Stille. There are, at the present time, two tubes in my laboratory which show the stage they have photographed, and several much purer tubes. In several of the latter type of tubes the negative bands are so strong that they can be observed visually on a direct vision spectroscope. In none of those tubes can we observe the nitric oxide or cyanogen bands. These have disappeared because of the purification of the nitrogen.

Reflection from the Ionosphere

THE conditions for the reflection of radio waves from the ionosphere are generally obtained by putting $\mu^2 \doteqdot 0$. But it is more correct, as was pointed out by Appleton[1], to obtain this condition by finding out when the group velocity vanishes. If we work out the conditions for the vanishing of the group velocity, neglecting friction, we find certain unexpected results. While for the ordinary wave there is only one condition of reflection given by

$$p = p_0 \quad . \quad . \quad . \quad . \quad (1)$$

(where p is pulsatance and $p_0^2 = 4\pi Ne^2/m$), the conditions for the extraordinary wave are found to be as follow:

$$p^2 - pp_H = p_0^2 \quad . \quad (2a),$$
$$p^2 + pp_H = p_0^2 \quad . \quad . \quad (2b),$$
$$p^2 - p_T^2 = p_0^2 \text{ (app)} \quad . \quad (2c),$$

where $p_H = eH/mc$, $p_T = eH_T/mc$, when we are using short waves. The first and second of these are those usually obtained for the extraordinary wave reflection. It is usually supposed that (2*a*) is the only one obtained, as (2*b*) is supposed to penetrate and to be absorbed. Toshniwal[2] was the first to observe and interpret the reflection corresponding to (2*b*). This has also been recently confirmed by Leiv Harang[3] working at Tromsø. The third is a new one and has not been so far reported.

It is well known that for the reflection corresponding to (2*a*), the difference between the penetration frequencies for the ordinary and the extraordinary waves is approximately 0·7 mc./sec. While this has been confirmed in this laboratory, Messrs. Pant and Bajpai, working after midnight, have several times observed the penetration frequency difference to be only about 0·14 mc./sec. This result at first appeared to be very puzzling, as it could not be accounted for on the existing theories. But it is easily explained as a reflection given by (2*c*). At Allahabad, $p_T^2 = 40{\cdot}5 \times 10^{12}$, and in the neighbourhood of 75 metres the difference between the penetration frequencies is 0·13 mc./sec. according to (2*c*). For higher latitudes (for example, England) this difference will be very small (for 4 megacycles, 0·03 mc./sec.) and it will be difficult to observe. It would be interesting to know whether similar results are obtained at other tropical stations.

Details of the calculation are being published in the proceedings of the National Institute of Sciences, India.

Who were the Picts?

IN the note in NATURE of December 19 (p. 1061) upon Dr. Bachmakoff's discussion about the evidence of a pre-Aryan population of southern Russia, he is quoted as suggesting that in France the Veneti were a pre-Aryan people "possibly related to the Picts". This lands one in the vexed question whether there ever was a race or tribe that assumed and bore the name Pict.

The earliest occurrence of that name in literature is in the chronicle by Ammianus Marcellinus (A.D. 326–391) describing under the year 364 how the Roman province in North Britain was continually raided by "Picti Saxonesque et Scoti et Attecotti". The "Pictish Chronicle", composed in the fourteenth century, begins with a quotation from the "Origenes" of Isidore, Bishop of Seville (560–636), as follows:

"Picti propria lingua nomen habent a picto corpore"; but it is to be noted that Bishop Isidore wrote "Scoti" not "Picti"—painted.

Hostilities which Great Britain had to wage in defence of her colony in South Africa at frequent intervals between 1809 and 1877 are still commonly termed the Kaffir War; but Kāfir is only an Arabic term for infidel or stranger, and none of the native tribes engaged in that war call themselves Kaffirs.

Nicknames were bandied pretty freely in the late European War; British soldiers speaking of their German foe as Huns, while the French termed them Boches. So in the fourth century, Ammianus Marcellinus, who was never in or near Britain, would hear the Celtic foes of the Empire commonly referred to in Rome as Picti.

HERBERT MAXWELL.

Monreith.

Points from Foregoing Letters

STRONG indications that a few females of the native oyster, *O. edulis*, can produce young at an age of little more than a year, are reported by a group of investigators from the University of Liverpool. The number of shelled and just coloured larvæ born by one of the females was estimated at 240,000. About 12,000 larvæ (in the trochosphere stage) were counted in a drop of liquid after three days settlement. The authors also give a graph showing the relative weight distribution, in one-year old English native oysters.

F. W. James, Dr. J. S. Anderson and Prof. H. V. A. Briscoe find that when complex cobaltammines are dissolved in partially heavy water, complete isotopic interchange takes place, as reported by Erlenmeyer and Gartner, but that it requires some hours. Since the exchange can be stopped by rapidly distilling off the water from the solution or, better, by precipitating the complex, for example, as the mercurichloride, $[Co(NH_3)_6]Cl_3.HgCl_2$, a kinetic analysis of the reaction is possible and is being undertaken.

Mr. W. C. Pei announces that a fifth skull of early man in China has been discovered, and that a preliminary report by Prof. F. Weidenreich will appear shortly on the new material.

A very minute effect has been found by the Michelson-Morley-Miller experiment for determining the absolute velocity of the earth. Prof. W. B. Cartmel states that if one of the arms of the interferometer is inclined at a different angle from the other, a very large fringe shift may be observed even with a small interferometer. The experiment is simple, and can easily be repeated.

An increase in the number of radio atmospherics observed in Paris and also at Tunis and Rabat on December 12, 1936, is attributed by R. Bureau to an improvement in the propagation of the long waves over a great distance. This seems to be due to the ionospheric perturbations following upon the solar hydrogen eruption observed on the same date and at the same time at Greenwich by H. W. Newton.

In answer to Prof. Synge's criticism, Prof. Leigh Page submits an example indicating that his relativistic theory is able to dispense, in certain cases, with both the concept of the rigid measuring rod and that of the isochronous clock.

A method for the measurement under the microscope of fog-, cloud- and rain-droplets is described by N. Fuchs and I. Petrjanoff. The droplets are collected on glass slides coated with a mixture of vaseline and mineral oil, which practically prevents the evaporation of the droplets, without affecting their spherical shape.

The preparation of a highly active apo-dehydrogenase (a non-dialysable and heat-sensitive colloidal carrier, protein in nature) which is an essential component in the fermentation of alcohol, is described by M. Sreenivasaya. The purified preparation is 135-fold more active than the original yeast extract.

The activity of the hormone progesterone in inducing ovulation in the South African clawed frog, *Xenopus lævis*, is described by Dr. H. Zwarenstein. Ovulation was induced not only in adult normal animals but also in a certain proportion of immature normal animals and in others from which the pituitary gland had been removed. The hormone also acts upon ovaries *in vitro*.

In *Pisum sativum* the genes R and A (R/r = round/wrinkled, A/a = coloured/white flowers) have hitherto been found, according to Miss Caroline Pellew, to be independent in the normal structural type The relation of these two genes in the three structural heterozygotes, found by Mrs. Sansome to have one interchanged chromosome, No. 1, in common, show that they are located in this chromosome in the normal structural type.

S. Paramasivan reports that the classical Jain paintings at Sittannavasal in South India have been executed in *fresco-secco* technique. He gives the results of analysis of the plaster and the pigments. Lime, carbon, yellow and red ochres, lapis lazuli and terre verte have been used as pigments.

S. Bhagavantam and Dr. A. Veerabhadra Rao have photographed the Raman spectrum of benzene vapour. While the principal line at 992 shows no shift, the line at 3061 in the liquid shifts to 3069 in the vapour and 3047 has not appeared in the vapour picture. Considerable alterations take place in the structure and intensity of the 'rotation wing' on passing from the liquid to the vapour.

The fact that Cario and Stille could not observe the negative bands of nitrogen and those first-positive bands which originate on vibrational levels higher than $v' = 14$, is due, according to Prof. J. Kaplan, to incomplete purification of the nitrogen in their discharge tubes.

R. N. Rai has calculated the conditions of reflection of radio waves from the ionosphere on the assumption that the group velocity vanishes. In addition to the usual results, a new condition for the extraordinary ray is found according to which the penetration frequency difference is only one fifth the expected results. This is in agreement with the observations made at the Physical Laboratory, University of Allahabad.

Research Items

Jungle Yellow Fever

ONE of the most interesting sections of the annual report for 1935 of the International Health Division of the Rockefeller Foundation deals with the occurrence and ætiology of what is termed "jungle yellow fever". This form of yellow fever is met with in Brazil in districts in or close to uncut forest or jungle, and in which the ordinary and only vector of yellow fever in town or city, the mosquito *Aedes ægypti*, is absent. One large area was discovered in 1934 in which more than sixty fatal cases had occurred, all with one possible exception acquiring their infection in rural areas in which this mosquito did not exist. Accumulated evidence suggests that jungle yellow fever usually occurs in man as an accidental infection secondary to an infection in a lower animal, much as bubonic plague occurs secondary to plague in rats and other animals. Evidence is presented that jungle yellow fever is secondary to the disease in the wild monkeys of the district, with transmission by mosquitoes of the genus *Hæmagogus*, for it was demonstrated that a large proportion of the monkeys of the district had a naturally acquired immunity to yellow fever, and that the infection could be experimentally transmitted by *Hæmagogus* sp. Work upon several other diseases—malaria, hookworm disease, diphtheria, yaws, tuberculosis and others—is surveyed in the report, as well as the aid given by the Foundation in furthering public health education throughout the world.

Genetics and Cytology of Hybrid Ducks

THE intergeneric hybrids between Aylesbury and Muscovy ducks have been studied genetically and cytologically by Prof. F. A. E. Crew and Dr. P. C. Koller (*Proc. Roy. Soc. Edinb.*, 66, pt. 3). Aylesbury ♀ × Muscovy ♂ produces sterile males and grossly abnormal females with rudimentary ovary and no sex behaviour. Both sexes have a crest. In the reciprocal cross, the males are sterile while the females have a normal ovary, lay small eggs and show normal sex behaviour. The females are uncrested. The chromosomes of the parent species show no visible differences, consisting in each of five pairs of long chromosomes and numerous tiny granules, the highest chromosome count obtained being 72. Spermatogenesis shows numerous abnormalities, including short or multipolar spindles, binucleate spermatogonia, chromosome elimination, supernumerary post-meiotic divisions and giant multinucleate cells. One chromosome in the hybrid commonly lagged on the spindle in meiosis, probably because of a short terminal inversion. Since this would be insufficient to account for the phenomena of sterility, and also because the parent species show differences in nuclear and cell size and in rate of embryonic development, it is suggested that the abnormal gametogenesis is due to genetic factors which do not affect chromosome pairing, but which affect the harmonious relationship between chromosomes and spindle. This is conceived to be a result of profound differences in cell metabolism between the parental genera.

Chalcid Wasps of the Genus *Harmolita*

TECHNICAL BULLETIN No. 518 of the U.S. Department of Agriculture (September 1936) is a brochure forming a second revision of the species of the genus *Harmolita* (*Isosoma*) of America north of Mexico. Its author, Mr. W. J. Phillips, was, until lately, entomologist in the U.S. Bureau of Entomology and Plant Quarantine. It is seventeen years since the first revision of the genus was published, and in the present communication some twenty new species are described. The members of the group show a remarkable specificity of their host preferences, and it is only very rarely that a species will develop in more than one species of host. The author adds that he has never known a species of *Harmolita* to oviposit in plants of different genera. The extensive key which accompanies this paper refers to the females only: in half the known species males do not normally occur. The basis of the revision is the author's discovery of a new character in the sculpturing of the ventral aspect of the petiole and of its point of fusion with the ventral sclerite of the abdomen. This character is used with reference to identification of the males, where it appears to be better than other characters, although less valuable than with regard to females. The genus is one of definite economic importance since some of its members attack certain cereals and cultivated grasses.

Japanese Bopyrids

THREE recent papers by Dr. Sueo M. Shiino deal with interesting new Bopyrids ("Bopyrids from Tanabe Bay (3)". *Mem. Coll. Sci.*, Kyôtô Imp. Univ., Ser. B., 11, No. 3; 1936. "Bopyrids from Shimoda and other Districts" and "Bopyrids from Misaki", *Rec. Oceanograph. Works in Japan*, 8, Nos. 1, 2 and 3; 1936). The first is a continuation of his work published in this same journal in 1933 and 1934. Several new forms are described, mostly from crabs or shrimps. The new genus *Cataphryxus* has been created for *C. primus* in a former paper called *Epiphryxus primus*, the generic name *Epiphryxus* having been used by Nierstrasz and Brender à Brandis to describe a phryxid *E. adriaticus*. The second paper also includes new species, the material being collected at Shimoda, Nagasaki and Formosa. The new genus *Heterocepon* is here created for an Ione-like Bopyrid, closely related to *Dactylocepon*, *Metacepon*, *Anacepon* and *Hypocepon*, all having well-developed endopodites in the female and the medio-dorsal process absent. A table shows the differences between these genera. The third paper includes species collected near the Marine Biological Station at Misaki.

Spores of the Mushroom

MISS D. M. CAYLEY has made a detailed study of the spores and spore-germination in wild and cultivated mushrooms (*Trans. Brit. Mycol. Soc.*, 20, Parts 3 and 4, November 1936). It has been stated that the wild mushroom has four basidiospores, and the cultivated form only two; but Miss Cayley has shown that two of the three common varieties in cultivation have a number of spores varying from one to four. The origin of the cultivated mushroom is very obscure, and the present paper does not illuminate this question; but mycologists will be greatly interested in the discussion of circumstantial evidence for heterothallism in the genus *Psalliota*. Spores of wild mushrooms are haploid, and it is suggested that *P. campestris* and *P. arvensis* may be haplodiœcious. The cultivated mushroom is a saprophyte, but there is a certain amount of evidence that the wild form may be a facultative parasite upon the roots of grasses.

Some Diseases of the Potato

MODERN knowledge has not brought a new cure for the fungus causing wart disease of potatoes, but numerous investigations have elucidated the incidence and pathogenic cycle of the disease. The Ministry of Agriculture and Fisheries has provided an admirable summary of modern findings in its new Advisory Leaflet No. 274, "Wart Disease of Potatoes". This replaces the old Leaflet No. 105, and perhaps the most striking addition is a list of solanaceous plants, other than the potato, which have been infected artificially with the causal fungus *Synchitrium endobioticum*. Such hosts do not, however, seem to play any practical part in spreading the disease under natural conditions. The subject matter of all sections of the leaflet has been entirely rewritten, and the list of immune varieties has been brought up to date. Advisory Leaflet No. 278, which replaces Leaflet No. 164, makes a clear presentation of the menace of the virus disease leaf roll to the potato crop. Rogueing diseased plants from isolated crops with very slight incidence of the malady, and fumigation of seed-tuber stores to eradicate transmitting insects, are the control measures recommended.

Glaciation of Bantry Bay District

THE results of a study of the evidences of the latest glaciation in the neighbourhood of Bantry Bay have recently been recorded by A. Farrington (*Sci. Proc. Roy. Dublin Soc.*, 21, No. 37; 1936). The area was invaded by an ice-sheet coming from the north-northwest over the ridge formed by the Caha and Slievemiskish Mountains, which were overwhelmed to a height of about two thousand feet. The Bay was filled with ice which escaped south-westwards along the Bay itself; north-eastwards into the mountain valleys, where fine terminal moraines are found; and south-eastwards as far as Skibbereen. The terminal moraine of this sheet can be traced for about twenty miles from the pass of Keimaneigh to Skibbereen. The press of ice coming down the Glengarriff valley was congested at the head of the Bay, and there is evidence of much differential movement within the ice-mass. Drumlin trains mark the north-east and south-west ice movements, but in the south-east direction they are poorly developed. The occurrence of erratics of typical crinoidal limestones of Lower Carboniferous type on the south shore of the Bay seem to have been derived from a former exposure of Carboniferous limestone which is now covered by the waters of the Bay. Otherwise they must have been carried from the outcrops at Kenmare without leaving a single example on the ranges to the north of the Bay.

Obtaining Upper Air Data

A RECENT report circulated by Science Service of Washington, D.C., deals with a new development of upper air research. The sounding balloon, with recording instruments that are not at once recovered, is not equal to the demands of modern weather forecasters for prompt information about the physical state of the upper air. This failure has led to the construction in various countries of devices carried by balloons which send out automatically, by radio, reports of pressure, temperature and humidity. The latest of these comes from the California Institute of Technology. Carried by a balloon 5 feet in diameter, and emitting on a wave-length of 1·7 metres, it has already yielded a sounding up to 30,000 feet. L. E. Wood, graduate assistant of the Institute, has designed the meteorograph, and has developed for it a 2-volt storage battery that weighs only 4½ gm. Fifty of these batteries are used in series in place of the ordinary dry battery system. The radio transmitting apparatus is the work of Capt. C. O. Maier, of the U.S. Signal Corps. A very small tube emits a constant signal, which is interrupted by a timing device that translates the data for broadcasting. It is a modified watch that develops twenty-five times the power of an ordinary watch. Power for the radio comes from three dry cells, of 135 volts in all, and three small storage batteries. The signals are recorded on an electrically operated tape.

A New Actinometer

As a result of experiments carried out in the laboratory of the Meteorological-Hydrographical Institution at Stockholm, A. Angstrom has produced a new design of actinometer. This is described under the heading "A Simple Actinometer" in paper No. 9 of the Institution reprinted from *Gerlands Beiträge zur Geophysik* (48, 303; 1936). The author suggests that in some ways it would be better to reduce rather than to increase the number of actinometers; but this one was designed and made for the glaciological expedition of Prof. H. Ahlmann to Iceland in the summer of 1936, and worked well, and as it was felt also that a very simple and portable instrument is in demand for meteorological work, it seemed desirable to publish a description of it. The new actinometer consists of a thermometer with blackened spiral bulb the plane of which is perpendicular to the graduated stem. Solar radiation is admitted through an aperture in the lid of a cylinder which surrounds the thermometer. At the bottom end of the cylinder is a Fuess aspirator similar to those used on psychrometers. When the inside of the apparatus has been brought to air temperature, which takes about two minutes, the aspirator is removed and the cylinder is trained on the sun with the aid of a diopter. An exposure of 90 seconds is made, and the rise of temperature is observed. This rise is for a particular instrument nearly proportional to the intensity of the solar radiation. The constant by which the rise must be multiplied to get the radiation intensity is found for each instrument by comparisons made with some standard instrument of more elaborate pattern. Figures are quoted which suggest that the error arising from the use of this simple actinometer will usually be less than three per cent, which for many purposes is quite accurate enough. An observation can clearly be made in a very short time.

Clarification of River Water

IN an account of an extensive series of experiments on the clarification of water from the River Vltava in Czechoslovakia (*Proc. Masaryk Academy of Work*, 10, 233; 1936), Prof. J. Milbauer concludes that crude aluminium sulphate is the most satisfactory clarifying agent for this and other river waters. In his investigations it was found that the addition of 100 mm. of the salt per litre gave the best results. Pure aluminium sulphate was not so satisfactory, probably because the silica and other impurities in the crude salt play an important part in flocculating the aluminium precipitates. The most suitable temperature was 10° C.; below this point flocculation was slow. Clarification was favoured by hydrogen ion concentrations up to pH = 4·2. Beyond this it decreased to a minimum at pH = 5·0. The addition of such substances as calcium hydroxide, ferric sulphate or silica had no perceptible influence, although addition of excess of charcoal was favourable to sedimentation. Cheap natural products like chalk, felspar, clay, dolomite powder, coal dust, peat or infusorial earth had no useful action on the process. Addition of colloids (proteins, saponine, silicic acid, etc.) were definitely detrimental, but kaolin and certain industrial wastes and the ash from a refuse-burning station were beneficial in assisting the flocculation of the precipitates from the addition of aluminium sulphate to the river water. Pre-treatment with ozone, chlorine, carbon dioxide or sulphur dioxide was not advantageous.

Magneto-optic Method of Chemical Analysis

THE work of Allison and others on the magneto-optic apparatus has been called into question by certain observers who have been unable to observe the 'minima' which are claimed to be characteristic of the substances under observation. Gordon Hughes has recently described a photographic method whereby small changes in light intensity have been successfully detected and the reality of minima conclusively demonstrated (*J. Amer. Chem. Soc.*, 1924; 1936). More than 2,300 photographs taken in this investigation show that there is a small effect—the change of light intensity for a minimum being 0·7 per cent—which is characteristic of the substance under test in the apparatus. Water-blanks showed approximately zero percentage change. The presence of foreign materials did not change the magnitude of the intensity change for a minimum. The direction of the effect was found to be dependent on the direction of the magnetic field in the coils, and to reverse with the setting of the Wollaston prism on either side of the critical 45° position. The measured photographic effect was found to occur only at positions of minima which had been previously determined by repeated visual observations It is concluded that the photographed effect is identical with the visual effect and that the latter is real, despite the not unexpected inability of certain workers to observe it

Locomotive Furnace Control

THE principle of furnace control by means of the carbon dioxide concentration in the flue gases is well known in its application to stationary units. In practice, conditions of firing and air supply are regulated, and heat losses in the flue gases (carbon monoxide and hydrogen) are eliminated by maintaining the carbon dioxide at a fixed optimum percentage. Measurement of the carbon dioxide content is frequently carried out by a thermal conductivity method, but unfortunately this is complicated by the fact that both carbon monoxide and hydrogen affect the readings of any thermal conductivity meter. On application of this principle to locomotive furnaces, where conditions of firing and air supply are not so readily controlled as in stationary plants, the presence of carbon monoxide and hydrogen has a very pronounced effect on the carbon dioxide meter reading. V. Binns and S. Bairstow, in a paper read before the Institute of Fuel on November 25, emphasized this factor and outlined investigations which had been made with the view of assessing the accuracy of thermal conductivity methods of gas analysis when applied to locomotive flue gases. Results of such investigations proved that this method can be adopted, providing appropriate corrections are made to meter readings. The method of correction is simple and is well illustrated in the paper by a rapid graphical method.

Strength of Materials

IN a paper entitled "The Relationship between Mechanical Tests of Materials and their Suitability for Specific Working Conditions" read before the North-East Coast Institution of Engineers and Shipbuilders on December 18, Dr. N. P. Inglis dealt with the various stipulations most or all of which are usually included in the specification of an important steel forging; he analysed critically each of these from the point of the useful information it provides and demonstrated, that for service under particularly severe conditions, such as high temperature, mechanical tests require to be supplemented by precise knowledge of chemical composition, method of manufacture, amount of ingot croppage and of hot work, and the nature of the heat treatment given. It was, however, also shown that from the ordinary mechanical tests, by the adoption of suitable procedure, much more than the usual amount of information could be derived and, as an example, the value of the Izod test both as a guide to the correctness or otherwise of heat treatment in certain alloy steels, and also as a means of indicating the presence of laminations or other effects of segregation, was quoted. In this last connexion, the position of the notch must be suitably arranged and, following from his discussion of this point, the author suggested that microscopic examination of Izod test fractures would add materially to the information of the mere figures of the test. Among other matters, the deterioration of mechanical properties under severe service conditions was discussed, and the results of two groups of notched bar tests were cited. The first of these referred to a number of samples of different qualities of steel subjected, during fifteen months' service, to temperatures of 410°–430° C., and it was here shown that while some samples depreciated to Izod values 14–80 per cent of their original figures, in others the initial value was fully maintained. In the second group, similarly varying results, arising from different preparatory treatment, were obtained in samples subjected to subnormal temperatures of − 30° C. while in service.

Mandibles of Peking Man*

THE late Dr. Davidson Black, honorary director of the Cenozoic Research Laboratory of the National Geological Survey of China, at the time of his lamented death was engaged on the study of the mandible of Peking man. Further material discovered since then has necessitated some modifications in the conclusions at which he arrived. This new material has now been incorporated in a study by his successor, Prof. Franz Weidenreich, in which he has been able to include the plates which Dr. Black had prepared.

The number of mandibles, or parts of mandibles, of *Sinanthropus*, which has now been obtained from Choukoutien, is eleven, of which six are juvenile and five are adult. [A further specimen was found in October last.] They are of both sexes. In his prefatory remarks, Prof. Weidenreich points out that the importance of the mandibles of fossil man has always been recognized, and given rise to considerable discussion, since the discovery of the Naulette jaw in 1866; but the jaw of *Sinanthropus* is of special interest. All the known lower jaws of fossil man, with the exception of Heidelberg and Piltdown, form a group which is distinguished from modern man in lacking a chin, in being more massive and bulky and in having the relief of the surface strongly developed. In these respects *Sinanthropus* conforms; but as the teeth constitute the essential factor in its classification, it is of importance to determine how far the lower jaw fits into the framework. Its significance is enhanced by the fact that, unlike the other jaws of fossil man, all the specimens come from one site, though from different levels.

In its bearing on the evolutionary problem, the evidence of *Sinanthropus*, the most primitive and geologically the oldest hominid known, is crucial. It should point the way to the solution of the problem whether the modern jaw is derived from an ape-like ancestral jaw by the retraction of the teeth and the development of the chin, modifying an original prognathism, or from a 'mesogeneiotic' form which develops on one side into the prognathism of the anthropoid, and on the other into the orthognathic form of modern man. The high antiquity of the Heidelberg jaw, combined with its resemblance to Neanderthal man, has been thought to militate against the former alternative, which demands that the earlier the jaw in a chronological sense, the nearer its resemblance should be to the ancestral type. On this question, the position of the Peking mandible should be decisive.

Prof. Weidenreich, after describing in detail the eleven mandibles now available, and recording and discussing their measurements, passes on to consider the peculiar characteristics of *Sinanthropus* and its comparison with other types, as well as the place of Peking man in the evolutionary scale, incidentally recording some interesting conclusions on *Australopithecus* and the Piltdown jaw.

As regards sexual differences, it is evident that two types, a large and a small, are represented in the mandibles. The idea that they belong to different races may be discarded. If the difference is due to sex, as is held, the ratio in size of female to male is much lower than in recent man, and more closely resembles that of the anthropoids. In *Sinanthropus* the ratio of small to large is 85·0 per cent; in modern man (Mongol), of female to male it is 92·4 per cent, in orang, 78 per cent, gorilla, 80 per cent and chimpanzee (approximately) 87 per cent.

As regards the special character of the mandible, the male is much larger, and bulkier than that of modern man; but this does not hold of the female, although the female ramus exceeds in height and breadth that of the Mongol of to-day. In height of body the symphysis height of 40 mm. reaches the upper margin of recent man, though the two measurements do not exactly conform. The *Sinanthropus* jaw has a higher alveolar and lower basal plane than modern man. The bicondylar breadth of 146·4 mm., it is interesting to note, is greater than that of the Eskimo, 140·0 mm., which is exceptionally broad, although the bigonial breadth, 108·6 mm. is below the Eskimo measurement of 130 mm. In both, measurements the female jaw is within the range of modern man. The angle of inclination of the frontal part of the jaw is the lowest known in hominids excepting the Heidelberg jaw, which is the same, namely, 60°. Another striking feature is the parallelism between the alveolar and basal planes, which is present also in orang and gorilla.

The shape of the alveolar arch presents a very characteristic picture in all adult specimens. Compared with recent man, the arcade shows a horseshoe-shaped, long and relatively narrow curve with its frontal part equally rounded in the region of the canines and incisors, and not flattened as in recent man. The free ends of the arches come close to each other.

In regard to the relief of the surfaces, one of the most outstanding features is the absence of chin (*mentum osseum*). In one specimen the area occupied by the roots of the frontal teeth is much larger than has been observed in any other known hominid, including the Heidelberg jaw. This feature, together with the strong inclination of the frontal part, points to a very primitive stage. There is, however, the beginning of a real mental spine, which has never been observed before in any of the Neanderthal mandibles, except La Chapelle-aux-Saints.

The juvenile mandibles exhibit the same qualities as the adult in regard to their bulkiness, even when sexual differences are considered. As to the anterior alveolar arch, it is noted, that in the only one concerned, it is much longer and more widely stretched than in recent man, and essentially longer than in the adult *Sinanthropus*. A distinct shortening takes place during dentition, in which *Sinanthropus* apparently follows modern man and differs fundamentally from the anthropoids.

In comparing *Sinanthropus* with other forms, Prof. Weidenreich records his agreement with Prof. R. Dart and Dr. R. Broom that *Australopithecus* is neither chimpanzee nor gorilla, but comes well within the human line of development. This conclusion he bases on the character of the teeth, which resemble those of *Sinanthropus* (to be dealt with in a later monograph) rather than those of chimpanzee or has already been completed. Now, with the approach of the Third Five-Year Plan, the activities of the Academy in this field are to undergo a decided change. Attention will be concentrated on key positions, and the number of the Academy's branches will be reduced, or handed over to the local authorities. A further function of the Academy is to study the cultural and economic achievements of mankind and to help in their rational application for the building-up of the new society. The main responsibility for this work falls upon the Social Sciences Section.

---

* The Mandibles of *Sinanthropus pekinensis*: a Comparative Study. By Franz Weidenreich. (Palæontologia Sinica, Series D, 7, Fasc. 3.) Pp. 162+xv plates. (Nanking and Peiping: National Geological Survey.)

The work of the Academy in the immediate future is to aid the State Planning Commission in the drawing up of the Third Five-Year Plan. The main efforts of the Academy's various institutes will be directed towards the solution of the following ten problems, outlined at a session held last March. (Needless to say, these problems do not comprise the whole work of the Academy and its research workers but, for the moment, they are the leading and dominant ones.)

(1) To develop geological, geochemical and geophysical methods of prospecting for useful minerals, particularly tin, rare metals and oil.

(2) To solve the problem of power by creating a unified electric power system throughout the U.S.S.R., with high-voltage transmission.

(3) To rationalize and extend the use of natural gas and by-product gas from industrial plants.

(4) To find a new type of fuel for internal combustion engines (study of chain reactions and explosion processes, internal combustion motor and electric automobiles).

(5) To rationalize technological processes in chemistry and metallurgy.

(6) To help in raising the grain yield of the country (research in seed selection, soil chemistry, plant biology, fertilizers and the mechanization of agriculture).

(7) To establish scientific bases for the development of animal husbandry and fisheries.

(8) To develop telemechanics (long-distance control of machinery) and to extend automatic processes in industry through application of theoretical physics.

(9) To draw up the balance sheet of the national economy of the U.S.S.R. so as to serve as a scientific basis for the Third Five-Year Plan.

(10) To study the history of the peoples of the U.S.S.R.

Science News a Century Ago

Robert Macnish (1802–37)

DR. ROBERT MACNISH, a brilliant physician and man of letters, who died on January 16, 1837, was born at Glasgow on February 15, 1802, the son and grandson of medical men. He obtained the degree of master of surgery at the early age of eighteen years, and first served as assistant to a general practitioner for eighteen months. He then went to Paris, where he attended the lectures of Broussais and Dupuytren and made the acquaintance of Gall, who pointed out Macnish to his fellow students as presenting a remarkable development of the organ of comparison.

On his return to Glasgow in 1825, Macnish obtained the degree of M.D. with a thesis on "The Anatomy of Drunkenness", which was published in 1827. Enlarged editions afterwards appeared and enjoyed a wide popularity. The work is of some historical value as being the first attempt to study drunkenness in its physiological aspects rather than as a crime. Macnish's next most important medical publication was "The Philosophy of Sleep", and was mainly based on the doctrines of Gall. His interest in phrenology is further shown by the publication in 1836 of an elementary treatise on the subject in the form of question and answer. At about the same time, he brought out a new edition of Amariah Brigham's "Remarks on the Influence of Mental Cultivation and Mental Excitement upon Health", to which he added numerous notes. He also contributed numerous articles to various periodicals, the best known of which, published in *Blackwood's Magazine*, was the tale entitled "Metempsychosis", which he wrote under the *nom de guerre* of "Modern Pythagorean". His collected tales, essays and sketches were afterwards published under this title with an account of his life by his friend Dr. David M. Moir. His premature death was due to an attack of influenza.

Production of Minerals in France

AT a meeting of the Statistical Society held on January 16, 1837, a paper by the chairman, G. R. Porter, was read entitled "A Statistical Account of the Mineral Products obtained in France during the year 1834; taken from official documents". In his opening remarks, the author said, that though in Great Britain no systematic effort had been made to gather statistics on the iron and coal mines, the French Government had recently deputed M. Le Play to ascertain the capability of every iron works and nearly every coal-field in England.

Mr. Porter's review of the mineral resources of France was divided under the following heads: ironworks; fuel; metals; salt, alum and copper ore; quarries, and operations connected with mineral substances. The quantity of iron ore obtained in France in 1834 was 1,551,473 tons, the number of smelting furnaces 374 and the weight of iron produced 221,886 tons. There were in use 97 furnaces for converting ore at once into malleable iron and steel, by a peculiar process used in Corsica, the production being 8,531 tons of iron and 399 tons of steel. There were also 1,230 forges for converting cast into malleable iron, and 1,556 rolling, drawing and slitting machines. The total value of the French iron manufacture was £3,492,519, and the number of men employed 31,704. Five sixths of the fuel used in iron manufacture came from the French forests. During 1834, 140 coal mines were being worked, and the coal produced was 1,550,530 tons.

George Richardson Porter, the author of the paper, was born in 1792 and died in 1852. Failing in business as a sugar-broker, he devoted himself to economics and statistics, and the Statistical Department of the Board of Trade was established mainly under his supervision. Among his writings was "The Progress of the Nation from the Beginning of the Nineteenth Century", the third edition of which appeared in 1851.

Rev. Baden Powell on the Dispersion of Light

AT a meeting of the Royal Society held on January 19, 1837, the Rev. Baden Powell, then Savilian professor of geometry at Oxford, read a paper entitled "Researches towards establishing a Theory of the Dispersion of Light". An abstract of the paper said:

"The author here prosecutes the inquiry on the dispersion of light which was the subject of his former papers published in the Philosophical Transactions for 1835 and 1836, extending it to media of higher dispersive powers, which afford a severer test of the accuracy of M. Cauchy's theory. He explains his method of calculation and the formulæ on which his computations are based. On the whole he concludes that the formula as already deduced from the undulatory theory, applied sufficiently well to the case of media whose dispersion is as high as that of oil of anise-seed: or below it, such as nitric, muriatic and sulphuric acids, and the essential oils of angelica, cinnamon, and sassafras, balsam of Peru and creosote. It also represents, with a certain approximation to the truth, the indices of some more highly dispersive bodies."

Faraday on the Views of Prof. Mossotti

The evening meetings of the Royal Institution, said the *Athenæum*, began on January 20, 1837, when considerable interest was excited by its being known that Faraday was to deliver a lecture on the views of Prof. Mossotti, of Corfu, who has lately promulgated an opinion, that one general law would account for those forces of matter which are exhibited in universal gravitation, cohesion, and electrical attraction and repulsion. Faraday began by observing that the want of such general law had been strongly felt, and had latterly been more than hinted at by Babbage, Roget and other philosophers. He went on to speak of the nature of the forces of gravitation, cohesion and electrical attraction and repulsion, and then, according to the *Athenæum*, said: "Hence there is such an adjustment of these forces, that at certain distances, matter acts inversely as the square of the distance, producing gravitation; but when the particles are nearer to each other, the powers are balanced, producing the state of cohesion; and when they are still nearer, they exert that repulsion, which keeps the particles of every solid and fluid body out of actual contact".

Robert Thornton (1768–1837)

Dr. Robert John Thornton, who was a prolific writer on botany and medicine, was born in 1768 and died on January 21, 1837. He received his medical training at Trinity College, Cambridge, where he attended Prof. Thomas Martyn's lectures, and at Guy's Hospital, where he was a pupil of the eminent surgeon Henry Cline. He qualified in 1793, and after further professional studies in Edinburgh, Dublin and Paris, and also in Holland and Germany, set up in practice in London, where he was for some time physician to the Marylebone Dispensary and lecturer on botany at Guy's Hospital.

At an early stage of his career, Thornton ruined himself by the publication of a magnificent folio in which contemporary artists and poets collaborated entitled "The Temple of Flora or Garden of the Botanist, Poet and Philosopher; with picturesque plates in illustration of the Sexual System of Linnaeus" (1799–1804). He was also the author of "Practical Botany" (1808), "The Philosophy of Botany" (1808), "Outlines of Botany or an Introduction to that Science" (1810), and "A Grammar of Botany" (1811). His medical writings included "The Philosophy of Medicine" (1799–1800), "Vaccinae Vindiciae or a Vindication of the Cow Pock" (1806) and "The Prevention and Cure of the Venereal Disease" (1817).

Societies and Academies

Paris

Academy of Sciences, December 14 (*C.R.*, 203, 1301–1406).

Louis Bouvier: Complementary observations on the claws of decapod crustaceans belonging to the Astacomorph section.

Serge Bernstein: The formula of approximate quadrature of Tchebycheff.

Jean André Ville: The convergence of the median of the *n* first results of an infinite series of independent experiments.

Frédéric Roger: The limits of a function at a point.

Alex. Froda: The properties characterizing the possibility of measuring multiform and uniform functions of real variables.

Bernard Salomon: Certain classes of reducers of oscillations of machine shafts.

Douchan Avsec: The ratio λ/h for vortices in longitudinal bands.

Jean Labat: The importance of Reynolds number in trials on small models. Results of an experimental study, using chronophotographs of particles of aluminium in suspension in water.

Charles Chartier: The structure of the general flow round a helix. Two diagrams based on a study by chronophotography.

L. Cagniard: The propagation of intumescences in directions with or against the current in rivers.

Bernard Lyot: The spectrum of the solar corona in 1936, wave-lengths and the intensities of the emission lines.

Daniel Chalonge and Horia Safir: Study of the variations of γ-Cassiopeia.

Mme. Marie Antoinette Tonnelat-Baudot: Relation between the action function and the force which acts on the electron.

Paul Soleillet: The interpretation of phase in the matrices of quantum mechanics.

Gabriel Duch: The determination of the surface tension of a liquid by the formation of drops at the end of a capillary tube in which the elongation of the meniscus is observed.

James Basset: Thermal exchanges in nitrogen and in hydrogen at ultra-pressures up to 6,000 kgm./cm.^{2}.

Marcel Laporte: The production of white light by the electrical luminescence of gases. The method is based on the production of discharges of very high intensity of very short duration through a gas (xenon), the discharges being repeated with a frequency sufficiently high to make use of the persistence of light impressions. In the arrangement described, the oscillating discharge has a period of 8×10^{-6} sec.

J. J. Placinteanu: The electronic nature of light.

Claude Charmetant: The electrolysis of ferrous chloride, bromide and iodide and of ferric chloride in mixtures of water and ethyl alcohol.

Jean Jaffray: The discharge spectrum in air of high-tension magnetos.

B. Rosen and Mlle. Nina Morguleff: Spectroscopic study of the constitution of sulphur vapour. Additional proofs of the existence between 3600 A. and 6000 A. of two absorption systems of sulphur vapour, one of which forms part of the principal system of S_2.

François Grisel: The flow of water, under constant pressure, through a mass of concrete. The volume of water passing through is a linear function of the logarithm of the time; hence the permeability of a specimen of concrete, under constant pressure, can be determined by measuring the volume passing during a relatively short time.

Gabriel Valensi: The kinetics of the oxidation of copper at a high temperature.

Jacques Bénard: Study of the stability of solid solutions between the lower oxides of iron and cobalt.

Maurice Dodé: Remarks on the conditions of possibility of heterogeneous reaction with a gaseous phase, in the case of miscibility of condensed phases.

Jean Cournot and Marc Baudrand: The corrosion of joints. Details of results obtained with riveted joints. For light alloys, cadmium-plated rivets give the best results. For joining steels, light alloy rivets without cadmium give the best autoprotection.

Etienne Vassy: The variation of the absorption coefficients of ozone and the temperature of the upper atmosphere.

Emmanuel Voyatzakis: The compounds of nitroprussides and hexamethylenetetramine.

Mlle. Alice Lacourt: Application on the microanalytical scale of the methods of quantitative organic analysis by hydrogenation.

Maxence Meyer: The synthesis of $\alpha\alpha'$-diethoxy-acids with straight chains.

Antoine Willemart: Researches on the dissociable anthracene oxides: the photoxides of 9-phenyl-10-methylanthracene and of 9-phenyl-10-ethylanthracene.

Georges Darzens: A new general method for the condensation of dichloracetic ester with ketones and aldehydes by the use of very dilute metallic amalgams. A general method for preparing compounds of the types $RR'.C(OH).CHCl.CO_2C_2H_5$ and $R.CH(OH)CHCl.CO_2C_2H_5$. The yields are high.

Léon Palfray, Sébastien Sabetay and Jean Kandel: The catalytic hydrogenation of α-ionone, ionol, dihydroionol, tetrahydroionol, dihydroionone, tetrahydroionone.

Henri Lefebvre and Georges Le Clerc: The thermomagnetic study of the iron catalysts utilized in the synthesis of hydrocarbons by the Fischer method.

Pierre Chouard: Building up the stem in the Monocotyledons.

Raymond-Hamet: A new alkaloid, formosanine, extracted from *Ourouparia formosana*.

Georges Fron: The fight against tracheomycoses in plants. An account of the beneficial effects of the neutral sulphate of *o*-oxyquinoline by increasing growth and combating attacks by fungi.

Albert Peyron, Jean Verge, Louis Blanchard and Pierre Goret: The genesis of interstitial cells at the expense of seminiferous tissue, in the embryonic testicle and in the seminome.

Georges Bourguignon and René Humbert: Double contraction and double chronaxy of normal striated muscle of man and mammals. Analysis by progressive currents.

Philippe L'Héritier: The appearance of differences of pigmentation between various strains of *Drosophila melanogaster*, wild type, as the result of a larval intoxication.

Mme. Véra Dantchakoff: The effects of a permanent treatment with folliculine on the male organism.

Mme. Paulette Chaix: The mechanism of the action on substances containing sulphur in glucose by *Propionibacterium pentosaceum*.

Mlle. Camille Chatagnon: The gastric secretion of bromine in the course of bromide therapeutics.

Gustave Guittonneau and René Chevalier: The sensibility of the *Azobacter* of the soil to the molecular structure of the monoxybenzoic acids. For the strains of *Azobacter* studied, none of the isomeric sodium hydroxybenzoates was toxic, but their food value depended markedly on the position of the hydroxyl group.

André Boivin and Mme. Lydia Mesrobeanu: Bacterial variations and complete *O* somatic antigen.

Fernand Arloing, Albert Morel, André Josserand and Louis Perrot: The stereochemical configuration of the organic basis and the antitumoral activity of the metallo-ascorbic complex compounds.

Melbourne

Royal Society of Victoria, November 12.

Elizabeth A. Ripper: Stromatoporoids of the Lilydale limestone. (2) Species of *Syringostroma, Stromatopora, Stromatoporella* and *Idiostroma* are described. A review of the whole fauna indicates that a high proportion of the species can be identified with forms occurring elsewhere in the Middle Devonian; three occur in the Helderbergian (Lower and lower part of the Middle Devonian) of North America, while only two are typical of the Wenlock limestone of Great Britain and the Niagaran of North America. The Lilydale stromatoporoid fauna has very little in common with that of the British Wenlock with which the Lilydale limestone has generally been compared, and should rather be correlated with European and North American Devonian faunas.

Kathleen M. Crooks: Studies on Australian aquatic Phycomycetes. An account of the systematic and physiological characteristics of twenty species of aquatic fungi collected in the vicinity of Melbourne.

Isobel Cookson: On *Saprolegnia terrestris* n.sp., with some preliminary observations on Victorian soil Saprolegniales. The forms identified from Victorian soils include—*Saprolegnia terrestris* n.sp., *S. megasperma* Coker, *S. anisospora* de Bary, *Isoachlya unispora* Coker and Couch, *Achlya apiculata* de Bary, *A. racemosa* Hilderbrand, *A. caroliniana* Coker, *Thraustotheca clavata* (de Bary) Humphrey.

R. T. Patton: Ecological studies in Victoria (4). Red box – red stringybark association.

Vienna

Academy of Sciences, October 22.

A. Sommerfeld: Klein's parameters α, β, γ, δ and their importance to the Dirac theory.

Josef A. Priebsch and W. Baldauf: Temperature effect with cosmic rays (from three years records of the ionization on the Hafelekar, 2,300 m. above sea-level).

Marietta Blau and Herta Wambacher: Distribution of α-tracks of the radium series.

E. Moles and T. Toral: The molecular groups $CO_2:O_2$ and $N_2O:O_2$.

G. Jantsch and E. Schuster: Determination of the solubility of mercurous oxalate.

Hans Strouhal: The terrestrial Isopoda collected by Dr. Franz Werner in Greece and the Ægean Isles.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, January 18

Royal Geographical Society, at 5.—Prof. David Brunt: "Climatic Cycles".

King's College, London, at 5.30.—Prof. J. G. Semple: "Projective and Abstract Algebraic Geometry" (succeeding lectures on January 25, and February 1, 8, 15 and 22).*

Royal Society of Arts, at 8.—Prof. P. M. S. Blackett, F.R.S.: "Cosmic Rays" (Cantor Lectures. Succeeding lectures on January 25 and February 1).

Tuesday, January 19

University College, London, at 5.—Prof. J. C. Drummond: "Problems of Nutrition" (succeeding lectures on January 26 and February 2, 9, 16 and 23).*

Eugenics Society, at 5.15—(at the Linnean Society, Burlington House, Piccadilly, W.1).—Dr. David Forsyth: "Heredity versus Environment—a False Issue".*

Royal Statistical Society, at 5.15—(at the Royal Society of Arts).—Major P. Granville Edge: "The Demography of British Colonial Possessions".

Engineers' Study Group on Economics, at 8—(at 23, Grosvenor Place, London, S.W.1).—Major L. Urwick: "The Contribution of Scientific Management to the Solution of Present Economic Difficulties".

Wednesday, January 20

Bedford College for Women, at 5.15.—Prof. R. G. Stapledon: "The Utilization of the Hill Lands of Great Britain to the Best National Advantage" (succeeding lectures on January 21 and 22).*

Royal Microscopical Society, at 5.30.—Annual Meeting.

Dr. R. S. Clay: "The Mechanical Development of the Microscope".

Institution of Chemical Engineers, at 6—(at the Chemical Society, Burlington House, Piccadilly, London, W.1).—Symposium on "Superphosphate—its History and Manufacture".*

Royal Entomological Society of London, at 8.—Annual Meeting.

Dr. A. D. Imms, F.R.S.: "Some Reflections on Recent Developments in Entomology" (Presidential Address).

Royal Society of Arts, at 8.—J. de la Valette: "The Study of Colonial Culture in Holland and France".

Institute of Chemistry (London Section), at 7.30.—Dr. C. Ainsworth Mitchell: "Some Recent Advances in the Scientific Examination of Documents".

Friday, January 22

Royal Institution, at 9.—Gerald Seligman: "The Nature of Snow".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Junior Investigator for Corrosion Research in the British Non-Ferrous Metals Research Association—The Secretary, B.N.F.M.R.A., Regnart Buildings, Euston Street, N.W.1 (January 20).

Civilian Education Officer (Grade III, physics or engineering) in the Royal Air Force Educational Service—The Secretary, Air Ministry (E.S.1), Adastral House, Kingsway, London, W.C.2 (January 20).

Two Senior Scientific Officers in the Explosives Directorate, Research Department, Woolwich, S.E.18—The Chief Superintendent (January 23).

Technical Officers (electrical engineering) in a War Department establishment at Woolwich—The Secretary, Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, N.W.1, (January 29).

Assistant Director of Horticultural Education to the Norfolk County Council—The Director of Agricultural Education, Agricultural Station Offices, Sprowston, Norwich (January 30).

Assistant Botanist in the Plant Breeding Institute, School Agriculture, Cambridge (January 30).

Director of the All-India Institute of Hygiene and Publi Health, Calcutta—The High Commissioner for India, General Depar ment, India House, Aldwych, London, W.C.2 (January 30).

Director of Pottery Research in the proposed Pottery Researc Association at Stoke-on-Trent—Sidney H. Dodd, Piccadilly, Tunstal Stoke-on-Trent (February 1).

Instructor Lieutenants (mathematics, physics, chemistry engineering) in the Royal Navy—The Director, Education Department, Admiralty, 5 Millbank, London, S.W.1 (February 8).

Assistant Meteorologists (Grades II and III in the Meteorological Office—The Secretary (S.2.E.), Air Ministry, Adastral House, Kingsway, London, W.C.2 (March 1).

Nuffield Professor of Clinical Medicine in the University of Oxford—The Registrar (April 17).

Assistant Surveyor of Lands in the Civil Engineer-in-Chief's Department, Admiralty, London, S.W.1 (mark envelope "A.S.L.").

Lecturer in Domestic Science in the Huguenot University College, Wellington, South Africa—The Office of the High Commissioner for South Africa, South Africa House, Trafalgar Square, London, W.C.2.

Electrical Supply in Great Britain

THE sixteenth report of the Electricity Commissioners which has just been issued[*] shows that the use of electrical energy in Great Britain is expanding very rapidly. Between April 1, 1935 and March 31, 1936, the consumption of electrical energy increased by 16 per cent as compared with the same period in 1934–35. Compared with the corresponding period in 1933–34, the increase is 47 per cent. A survey has been made from which it appears that at the end of 1934 the areas of supply of the 625 electrical undertakings contained more than 12 million premises, of which 53 per cent were connected to the public supply systems. Of the total number, 85 per cent were domestic premises, and 52 per cent of them were connected with supply systems. With regard to electricity charges, two-part tariffs for domestic supplies were being offered by 81 per cent of the supply companies. The fixed or service charge of the tariffs was based on a variety of principles, the most common being the rateable value of the premises (217) and, next to this, 161 undertakings based their charge on the size of the premises. Of the supply systems, 398 offered a two-part domestic service with a running charge of 1*d.* or less per unit, and in 105 of them the running charge was ½*d.* per unit or less. In addition, statistics are given of the undertakings which offer 'assisted wiring schemes' and of those which provide showrooms or make arrangements for 'house to house' canvassing.

While the survey reflects the great progress made in the development of the public supply of electricity since the end of 1934, it also discloses the great potentialities still before the supply industry. There are still nearly six million unconnected premises, of which 87 per cent are domestic, and there are also great possibilities of a much-extended consumption for existing and additional purposes in the premises already connected. The existence of the Grid makes it possible to supply on much more uniform terms and in particular to offer a two-part domestic tariff with a low unit charge.

A recent event of particular interest to the electricity supply industry was the appointment by the Government, in July 1935, of a committee to consider and report upon the organization for the distribution of electricity in Great Britain. Its report was published in June last[*] ; the committee is usually referred to as the McGowan Committee.

Another report, published quite independently by Political and Economic Planning[†] (P E P), is of interest and value. The individuals who form the group P E P prefer to remain anonymous. They are a non-party group, who are by vocation industrialists, officers of central and local government boards, university professors, etc. The group has already issued nearly ninety broadsheets, to many of which reference has been made in our columns, as well as long reports on coal-mining, the cotton and iron and steel industries. The present report extends to 70,000 words and contains 40 tables of statistics. The instructions to the group of experts who wrote it were that they should present the facts about the electric supply industry of Great Britain, including the Grid, and prepare constructive proposals for making electricity more widely and cheaply available. The report does not conflict seriously with that of the McGowan committee.

---

[†] P E P (Political and Economic Planning). Report on the Supply of Electricity in Great Britain . a Survey of Present-day Problems of the Industry with Proposals for Reorganisation of Electricity Distribution. Pp. vi+171. (London : P E P, 16 Queen Anne's Gate, S.W.1 (1936).) 6*s.* net.

From the consumer's point of view, there must be in the first place a supply readily available at cheap rates. There must be the necessary service and credit facilities, so that the cost of wiring, of appliances and of maintenance is not a heavy burden on the consumer. There must also be a method of charging which is reasonably simple to understand and which, so far as possible, follows the same lines all over the country. Finally, a standard voltage and frequency must enable appliances to be interchangeable, so that the consumer is not stranded with useless apparatus and the manufacturer loaded with inflated costs owing to having to supply an unnecessarily wide range of appliances for different voltages or frequencies or both.

Looking back over the last fifty years, it is seen that as the result of falling costs, cheap electricity plays a part in the life of a nation entirely different from that played by expensive electricity. The difference is one of kind and not one of degree. "As yet the limits of future development are not only not in sight but are beyond conjecture."

The Electricity Commission's major function is that of granting powers under statute to supply electricity. Local authorities must obtain the consent of the Commissioners, if they want to borrow money for electricity purposes, such as building new generating stations or extending existing ones. This led to the formation under the Act of 1926 of the Central Electricity Board, which performs for the whole country the coordination of generation and high-tension transmission which had been intended by the Act of 1919 to be done on a regional basis. The Board has no financial control over authorized undertakings, but it can force owners to form part of the national supply scheme. In the event of refusal, the station can be compulsorily acquired. Generation and distribution have been dealt with in this way. Schemes for more 'regions' have been carried into effect, and trading has begun in most of them. Electricity supply is available in bulk at tariffs of uniform type in all these regions, but the activities of the Board do not extend beyond the ends of the transmission lines.

The PEP report points out that on the distributive side the prospect is less reassuring. The areas served by the hundreds of undertakings selling electricity to the public range from less than one square mile to 5,000 square miles, with widely different densities of population. Areas also vary widely in their wealth, their rates and many other factors. These numerous authorities record a considerable range of prices and methods of charging. There are several undertakings with a badly designed and inefficient system of supply (in one or two cases the units sold are only about 50 per cent of the units generated or purchased !). Credit facilities for the hire and hire-purchase of wiring and appliances seem abundant, and no efficient company should have any difficulty in finding the money to provide consumers with such facilities.

One of the fundamental problems for the supply industry is the price to charge the consumer. Should the best policy be to make each class of consumer equally profitable, in proportion to his consumption, to the undertaking, or should (as the railwaymen say) "the fat traffic pay for the lean" ? Should rural consumers be helped by urban consumers ? The PEP report offers no solution to this problem.

The all-in 1*d*. a unit with a slot-meter used in certain working-class housing schemes is mentioned. It is successful in the East End of London, but future development of such a simple tariff demands close study. The report says that many supply undertakers are backward in their attitude to fundamental marketing studies ; economic investigation would help them to provide a sound basis for long-period planning. Rural area supply is handicapped by the absence of trained specialist salesmen. Melton Mowbray is quoted as an example of excessive rating. In this town, local rates exceed in amount the whole cost of the electricity purchased from the Central Board together with the cost of the coal required for local generation.

The final chapter in the PEP report deals with the re-organization of electricity distribution, and is of real value. The recommendations are brief and overlap largely those of the McGowan Committee. Five proposals for legislation are suggested. First, that the Government should in consultation with the Electricity Commissioners appoint a committee of investigation. Six problems are stated in the terms of reference, agreed solutions of which would be a great help. Secondly, that an electrical development authority should be appointed with a constitution similar to that of the Central Electricity Board. The main functions of this body would be development and research, transfer and administration of purchase rights, publicity, statistics and design. This authority should have the power to finance practical experiments in the application of electricity to agricultural, industrial and commercial uses. It is also suggested that it should have the power to set up a central institution for the testing of consumers' appliances and equipment. Thirdly, the powers of the Electricity Commission should be increased. Fourthly, existing legislation on electric lighting should be co-ordinated and simplified; and lastly, certain anomalies and restrictions should be removed.

To a large extent, as we have said above, the conclusions and proposals of the P E P report coincide with those of the McGowan Committee. Both reject nationalization—at least at the present stage of evolution of the electrical supply industry. Both bodies prefer to proceed by the method of overhaul and consolidation and more efficient grouping of existing undertakings on a regional basis. The P E P proposal to set up an investigating committee is similar to the proposal of the McGowan Committee to set up district commissioners. The latter committee accepts as a guiding principle that larger undertakings are the remedy for present distribution difficulties, and contemplates schemes of amalgamation. The former committee sees some disadvantages in this. The P E P committee concludes by saying that "The public expects that the supply industry should hasten towards a future in which the maximum amenities will be available for the residential consumer, farmer and industrialist through the fullest freedom to use electricity".

Civilizing Science

(1) A Hundred Years of Medicine
By Wyndham E. B. Lloyd. (The Hundred Years Series.) Pp. 344. (London: Gerald Duckworth and Co., Ltd., 1936.) 15*s*. net.

(2) The Next Hundred Years:
the Unfinished Business of Science. By Prof. C. C. Furnas. Pp. xx + 366. (London, New York, Toronto and Melbourne: Cassell and Co., Ltd., 1936.) 8*s*. 6*d*. net.

(3) A Short History of the Future
By John Langdon-Davies. Pp. xxi + 272. (London: George Routledge and Sons, Ltd., 1936.) 10*s*. 6*d*. net.

THESE three books have two things in common. All of them attempt to link the present with the immediate past or the immediate future, by way either of historical summary or extrapolative prediction. All of them, almost inevitably, are largely devoted to considering scientific or technological development; to call this development progress would be to beg the question raised continually by two of them.

(1) Prof. Lloyd's book is the most specialized and the staidest of the three. How much so may, perhaps, be illustrated by quoting the second sentence of his final chapter, "Epilogue". He writes: "Any attempt to predict the purely medical developments of the future would be extremely rash". But the author's caution does allow him to go so far as to say "that we are not using to the full even the knowledge that we have". His short expansion of this statement, though guarded to the point of indiscretion and including an unpleasant and snobbish reference to "the masses", again links his book thematically with the other two. In any event, it may be fairly said that books like this contribute much of the raw material out of which books like those of Prof. Furnas and Mr. Langdon-Davies are built.

The introductory part of the book makes a rapid survey from "The Origins of Medicine" through the eighteenth century to the nineteenth. Chapters are included on surgery, the hospitals, the sanitary condition and health of the people, some common infectious diseases, the organization of the medical profession and "The Sources of Modern Scientific Medicine". In Part 2 the author gets down to his central subject matter, and ranges over the whole of medical development in "the last hundred years". The new pathology, based on the cell theory; newer methods of diagnosis; anæsthetics; nutritional studies; the 'germ theory', antisepsis and vaccine therapy; hormones, vitamins and radiological methods; such is the wide field surveyed in some 140 pages. In Part 3 the author writes of "Health Organization", both hospital systems and State medicine being examined, and so to the "Epilogue", to which reference has already been made.

The accuracy of Prof. Lloyd's statements of fact could only be judged adequately by a board —and obviously a very large board—of specialists ; the simple reviewer must analyse by sample. For example, it is entirely incorrect to imply that synthetic adrenalin still consists of an optically active mixture of isomers ; see the 1932 British Pharmacopœia. The account of liver treatment for pernicious anæmia, on the other hand, though brief, is unexceptionable, as is most of what he has to write about the vitamins. But in a book published in 1936, there seems little justification for closing the vitamin C story with Szent-Györgyi's brilliant isolation of ascorbic acid, and making no reference to the equally sensational simultaneous syntheses by Haworth and Rechstein in 1933. However, for the student of medicine, in the widest sense, as well as for the medical student, this book, in spite of the absence of any strikingly original concepts and in spite of the slight austerity of the author's approach and style, should prove thoroughly informative and useful, and it makes an excellent addition to Duckworth's "The Hundred Years Series", of which it is the fourth in five.

(2) Prof. Furnas's exasperating, stimulating, indignant, encyclopædic, wrong-headed, fervid, naive volume is altogether another pair of sleeves. Paradoxical in the extreme is the effect made by his attempt to show what tremendous distances science has to travel, for he could only do this by making abundantly clear how astonishingly long is the road already travelled, and at how breakneck a speed. The author works steadily through the sciences, or the main groups of sciences—biology, chemistry, physics and engineering—and concludes with three chapters on "Social Consequences" and a rather piquant "reading list" that ranges from Paul de Kruif to the U.S. Census, from the *Journal of Biological Chemistry* to *Time*, and from Wells, Huxley and Wells to Andrade.

The method of sampling applied to this book does not inspire over-confidence in the author's meticulous accuracy, as witness the statements about thyroxine that "Kendall and many helpers worked upon its exact molecular structure. An Englishman, Harrington, was also extremely active. These two . . . finally came to agreement". Truly, some of the worst examples of insularity come from people who live on the largest continents ! The trans-Atlantic origin of this book—Prof. Furnas occupies a chair of chemical engineering at Yale—is shown not only by the innumerable American examples used to illustrate the arguments, but also by the characteristic tang of the writing (possibly originating in part from the author's *Time* studies) and his inability to resist the epigrammatic 'wise crack', at whatever stretching of scientific accuracy. His advocacy of Epsom salts for preventing milk-fever in cows is scarcely in accord with the most scientific veterinary practice, and his declaration that vitamin C is "practically non-existent in animal tissues" is unnecessarily contemptuous of the adrenal cortex and many other tissues ; nor ought he to be puzzled about the source of vitamin D for tropical peoples who live mainly on vegetable food. On the other hand, his attack on the stream-lining of low-powered automobiles appeals to the commonsense of the user, if not to the pockets of the maker, but it is rather a schoolboyish jest to say of the second law of thermodynamics that "There is no danger of that law being repealed".

In spite of Prof. Furnas's attention to social phenomena, and his obvious concern with their bearing on scientific progress, he shows a curious blindness to the *reciprocal* effects of the two sets of forces—man's action on his environment conditioning the environmental forces that in turn act on man. While admitting up to a point this reciprocity in the world of machinery, he does not seem to have realized its far wider social implications, nor to conceive it possible that the complete change in social organization, which he somewhat reluctantly admits to be ethically and scientifically necessary, may be unexpectedly accelerated by changes in man himself, brought about largely by those very technological advances Prof. Furnas considers at present so incomplete as to be merely embryonic.

(3) Mr. Langdon-Davies, by profession an anthropologist, makes no such mistake ; he errs on the other side It is not in the least that he is unaware of actual or potential progress in applied science. For some years now he has been one of our leading popularizers of science ; his own training has given him the necessarily objective and experimental outlook, while his education in the humanities has given him a directness, accuracy and flexibility of style that should be the envy of all purely scientific writers and most other popularizers. As an example of irony in the tradition of Swift and Samuel Butler, the reader should study Mr. Langdon-Davies's examination of the Government's proposals for safeguarding the civilian population from gas attacks.

In his book, Mr. Langdon-Davies presents us with a plethora of alternatives. Peace or war ; Fascism or Communism ; free-will or determinism ; monogamy or polymorphism. He appears to see human evolution as a struggle between man's instrument of reason and the "social habit". His personification of this habit strikes me, at any rate, as curiously anthropomorphic. Mr. Langdon-Davies, I submit, has taken far too little into account the effect on that social habit both of man's reason directly and, much more important, of the environment created by man's reason.

However that may be, and whatever relative emphasis we place on the forces so differently emphasized by Prof. Furnas and Mr. Langdon-Davies, both books are thoroughly well worth reading. "The Next Hundred Years" is chiefly commendable for its survey of the vast field of man's technical adventures already achieved, and only incidentally for its author's views about present or future. "A Short History of the Future" also fails to convince in its prophetic vein, but is of great value in its ruthless analysis of the world to-day around us, a world that is in grave danger of passing out of the control of forces that alone could ensure peace and prosperity for the whole of mankind. As controlling influences, democracy and science have hitherto played unequal and unco-ordinated parts, but only those two forces, and only those two forces acting together in every department of man's social activity, can avoid the catastrophe the coming of which Prof. Furnas dimly and shrinkingly senses. Mr. Langdon-Davies, on the other hand, fully realizes the danger and faces it with pointed irony and a quite brutal bluntness; scarcely anyone could read his book without being healthily shocked.

A. L. BACHARACH.

The Mind of a Medieval Cleric

Opicinus de Canistris:
Weltbild und Bekenntnisse eines Avignonesischen Klerikers des 14 Jahrhunderts. Von Richard Salomon. Mit Beiträgen von A. Heimann und R. Krautheimer. (Studies of the Warburg Institute, edited by Fritz Saxl, Vols. 1A, 1B.) Textband. Pp. viii+348. Tafelband. Pp. v+45 plates. (London: Cassell and Co., Ltd., 1936.) Paper, 50*s*. net; cloth, 57*s*. 6*d*. net.

A CURSORY glance at the volume of plates, reproducing for the first time a Vatican MS. of the early fourteenth century (*Cod. Pal. Lat.* 1993), might lead one to dismiss it as a mere curiosity, so strange is the jumble of fact and fancy displayed by the drawings. But this would be a mistake, for, as is clearly shown in the learned commentary which accompanies it, the work throws many interesting side-lights on the life and ideas of the late Middle Ages.

The MS. was virtually unknown until a few years ago, when attention was directed to it by the distinguished Vatican Librarian, Cardinal Ehrle. Independently of each other, two scholars have since examined it in detail, and one of them, Dr. F. Gianani of Pavia, published his results in 1927. He concerned himself chiefly with another MS. of Opicinus—his panegyric upon Pavia, his early home—an anonymous work to the authorship of which the present MS. has first given the clue. It does him credit by its intimate knowledge of Pavia under all aspects, as well as by its judicious tone, in which it differs markedly from his other known writings. The present study is of wider interest, and Dr. Gianani's previous work in no way renders it superfluous.

Without the autobiography, the proper understanding of the Vatican MS. would have been still more difficult than it is. In his youth, the author's circumstances were far from easy and his education was somewhat fragmentary. After trying various occupations, he eventually became a cleric, but never advanced to any of the higher offices of the Church. Pavia was then distracted by the struggle between Guelfs and Ghibellines, and his advocacy of the Papal side forced him into exile, whereupon he betook himself to Avignon, and obtained a post as scrivener in the entourage of the Pope. There, in 1335, he began the present MS., and it could scarcely fail to be influenced by its *milieu*—a focus of the most varied currents of medieval life.

The parchment sheets offer a bewildering mixture of drawings and notes scattered over the whole surface, sometimes with no obvious connexion, and it needed the most persevering study to decipher and explain the whole. In this Herr Salomon has been singularly successful, and has wisely recorded the results in full detail, for few readers would have the knowledge or patience to unravel the puzzle for themselves. A recurring feature in the drawings is the map of the world, and the relative accuracy of its outlines shows at once that Opicinus deserves the credit of having followed the best models then available. It was just the time when the better knowledge previously confined chiefly to sailors was becoming more widely diffused, thanks largely to the cartographical work of Petrus Vesconti, one of whose maps may well have been known to the author. But whereas such maps did little for the interior of the lands, Opicinus shows a better knowledge in this respect than most of his contemporaries

Characteristic of the Portolan type of map is the close network of direction lines, in the careful drawing of which Opicinus seems to have taken a special pleasure. The strange thing is the way in which he used this correct knowledge as a starting point for wild flights of fancy, converting the outlines of land and sea into allegorical figures, and adding others to give a general picture of the religious side of life. The world-map seems to typify sin, as when it overlies the picture of Lazarus bound in grave-clothes, while the cure of sin is represented in another sheet by the healing streams typified by the system of the Po, *superimposed*, on a larger scale, on the general map. Quotations from Scripture abound, and here and there Old Testament curses are launched against the rival political party in Lombardy. Besides the maps, geometrical figures, especially circles, are freely used, and various sheets give attention to the calendar and astrological subjects, with the signs of the Zodiac and other associated symbols. In all this, Opicinus shows no decided break-away from current ideas, his originality consisting in the way in which he represents them graphically.

The drawings show no definite order and were composed at different dates. Much that is abnormal may be explained by a serious illness mentioned in the autobiography—of the nature, it would seem, of a paralytic stroke. The author is morbidly self-centred, obsessed with a consciousness of personal sin, though at times he goes to the other extreme and claims to be an inspired teacher. Students of mental pathology might find an interest in the work from their own point of view, while the drawings are not without value for the history of art and architecture, as is shown in two appendixes contributed by other hands.

The Warburg Institute deserves great credit for undertaking this publication. E. H.

The Study of Bird-Song

Songs of Wild Birds
By E. M. Nicholson and Ludwig Koch. (Bird-Lovers' Manuals.) Pp. xxxi+216+18 plates. (London: H. F. and G. Witherby, 1936.) With 2 gramophone records, 15*s*. net.

MR. NICHOLSON has given us a book which, although in the form of a popular manual, is much more than a presentation of established facts. It indeed makes a real contribution to a neglected subject, giving the results of original observation and usefully indicating lines of further research. It has additional novelty, through the enterprise of Messrs. Witherby, in being a 'sound-book'—illustrated by gramophone records as well as by pictures. To these remarkable records of birds singing in the wild state reference has already been made (NATURE, Oct. 10, p. 610): the text now before us includes a chapter by Mr. Koch telling how they were obtained, and an appendix giving a detailed key to their contents.

Biological interest centres on the part which song plays in the life of the bird, a matter which is still very little understood. From a functional point of view, Mr. Nicholson tentatively distinguishes four different levels. At the simplest of these, song seems to serve no very definite purpose beyond possibly expressing a feeling of well-being: at this level, song is very near the 'sub-song' which more accomplished species exhibit in addition to their louder and more definite music. At the next level a sexual factor is added, in that song is used as a stimulus in courtship. Still higher, there is also an element of advertisement, in announcing the presence of an adult male in breeding condition. In the extreme case there is a definite association with territory, and the song assumes the character of a challenge in addition to its other functions. In the British Isles at least, the species which utter typical loud song are all holders of individual territory, and the song is used by the male mainly in relation thereto.

The evolution of song presents a problem with several aspects. It is only the most highly developed birds, the passerines, that possess the anatomical apparatus necessary for producing the best type of song. On the other hand, among the species with this equipment, there is great inequality in the extent to which command over the voice has been achieved. Thirdly, Mr. Nicholson points out, even when both conditions are fulfilled, there must also be an adequate incentive among the conditions of life of the particular species, especially as regards its territorial and sexual behaviour. "A bird such as the starling has the equipment and the skill of a first-rate songster, but he is not one, presumably because song has not assumed an important enough function in his life to make him sing for all he is worth."

Apart from their function, songs are provisionally classified by Mr. Nicholson in four groups according to their structure. There are highly developed songs such as the music of the blackbird; finished song-patterns such as that of the chaffinch; and more primitive types, including rambling or indistinct utterances of low carrying power such as the twittering of the swallow. Finally, there are many breeding notes and song substitutes, such as the call of the cuckoo: and here also may perhaps be included some non-vocal sounds such as the 'bleating' of the snipe.

About half of the book is occupied by a useful account of the songs of different British species. Mr. Nicholson recognizes that musical notation is of little service in transcribing sounds which lie largely outside the range of the instruments of human art; and that attempts at phonetic representation in words or syllables have at most a mnemonic value. He therefore rightly aims at a more objective method of description, and in this he makes full use of exact timing of the length of the song, or of particular portions of it, and of the customary interval between each repetition. It is only in this way that accurate study can be made of such questions as local variations in the song of a species. Cases of regional 'dialects' are already known, and further study is desirable.

The book is full of welcome information and stimulating suggestion. With its accompanying records, it will surely be a source of both interest and pleasure to many. A. L. T.

Elementary Mineralogy

(1) Mineralogy:
an Introduction to the Study of Minerals and Crystals. By Prof. E. H. Kraus, Prof. W. F. Hunt and Prof. L. S. Ramsdell. Third edition. Pp. ix + 638. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 30s.

(2) Mineralogie
Von Prof Dr. R. Brauns. (Sammlung Göschen, Band 29.) Siebente, verbesserte Auflage. Pp. 146. (Berlin und Leipzig: Walter de Gruyter und Co., 1936.) 1.62 gold marks

(1) THE popularity of "Kraus and Hunt", first published in 1920, has led to the appearance of a third edition and the enrolment of a third author. Some sixty further illustrations have been added to an already lavishly illustrated book, and there is additional material on physical properties, the polarizing microscope, crystal structure and X-ray analysis, and the formation and occurrence of minerals.

The first 226 pages are devoted to crystallography and the physical and chemical properties of minerals; the next (and briefest) section contains descriptions of 150 of the commoner species, while the remainder of the book, printed on paper of a different tint, contains determinative tables based principally on the characters of lustre, hardness and streak. The illustrations, which form so attractive a feature, include photographs of wooden crystal models, well-known mineralogists and mineral specimens. The latter are notoriously difficult to produce successfully, and there are many here which are of doubtful value as an aid to identification. Interesting information on the commercial uses of minerals is given in a special chapter, and a brief chapter on gem-stones is designed to introduce the student to an attractive branch of mineralogy in which the senior author is a specialist. In another chapter, the fundamentals of X-ray crystal analysis are clearly explained and a valuable note on the structure of the silicates, as recently determined by X-ray methods, serves to clarify the complexity of this important class of minerals. Chemical (blowpipe) methods for identification are given in unusual detail.

There are some unexpected omissions. Goniometric methods are not even mentioned (the word 'goniometer' is not to be found in the index), and, while values for $2V$ are usually given for each species, interfacial angles are not so given. The hydrostatic and heavy-liquid methods for determining specific gravity are not described, as the authors consider that "these methods are very accurate but time consuming. They are generally employed in mineralogical research and but rarely by students of elementary mineralogy". It is strange that the use of heavy liquids, by which more rapidly than in any other way the density of a small fragment of mineral can be determined, should be dismissed as "time consuming", when a description of the far more time consuming pycnometer method has been included.

In the descriptive portion, the specific gravities accorded to each species represent the extreme range, with no indication of the normal value for reasonably pure specimens of the mineral in question. Refractive indices, however, are usually given to three places of decimals as though constant for the species, no variation being indicated.

The book is chiefly to be recommended for its clear and attractive presentation of the subject: only in the literal sense of the term (it weighs three pounds) can it be said to make heavy reading.

(2) Into this miniature text-book, which would not seriously embarrass a jacket pocket, Dr. Brauns compresses a description of some 120 minerals, preceded by introductory pages dealing with crystallography and such easily determined properties as streak, hardness and specific gravity. The optical properties of minerals, except dichroism, are not mentioned. B. W. A.

British Rainfall, 1935:

the Seventy-fifth Annual Volume of the British Rainfall Organization. Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1935 as recorded by over 5,500 Observers in Great Britain and Ireland. (Air Ministry: Meteorological Office. M.O. 395.) Pp. xvi+285. (London: H.M. Stationery Office, 1936.) 15*s*. net.

THIS detailed account of the rainfall of 1935, based on returns from more than 5,500 co-operating observers, is the seventy-fifth annual issue of the series begun in 1861 by G. J. Symons, founder of the British Rainfall Organization. Like its predecessors in the series, the present volume includes maps, tables and descriptive matter dealing with the distribution of the rainfall each month and for the whole year, studies of heavy falls on individual days of particular interest and data in regard to rainfall duration, evaporation and spells of dry or wet weather.

The statistics show that the year's rainfall was about normal in Ireland; in other regions there was an excess averaging thirteen per cent over England and Wales, eight per cent over Scotland and nine per cent over the British Isles as a whole. During October, 22·92 inches fell at Inverary Castle, Argyllshire, and on February 15 a fall of 6·16 inches was measured at New Dungeon Ghyll Hotel, Westmorland. On the other hand, both March and July gave exceptionally low totals in certain areas.

The issue contains two special articles; one of these gives details of the remarkable hail-storm which occurred in the early morning hours of September 22 over Northamptonshire, probably the most destructive hail-storm that has occurred for many years in the British Isles. The other article, by the Superintendent, deals with the frequency of occurrence of heavy falls in short periods. An analysis of ten years autographic records leads to a new empirical formula connecting the rainfall amount, the time of fall and the frequency. On the basis of this formula, the curves used for defining "noteworthy", "remarkable" and "very rare" falls have been drastically revised. It is also suggested that data computed from the formula should form the basis of sewer and drainage works design.

Tools of To-morrow

By J. N Leonard. Pp. vii+303. (London: George Routledge and Sons, Ltd., 1935.) Cheap edition, 5*s*. net.

IT is a truism that military leadership has seldom foreseen the conditions under which the next war would be fought, and has tended rather to plan its strategy and tactics in accordance with the experience of previous decades. The rate of impact of science on society is now increasing, or rather the period of industrial gestation is decreasing so rapidly that over whole spheres of our industrial and social life a like condition tends to prevail. Mr. Leonard could well have anticipated for this book the title of Sir Josiah Stamp's presidential address at Blackpool to the British Association. He is concerned with the impact of science upon society and with the means of adaptation and change which science has put into our hands. The book, which is admirably written, can be commended to all who seek to form an intelligent opinion on social and technical change and the numerous grave problems arising out of them. While avoiding the sensationalism of many journalistic efforts in this field, it is lucid and always stimulating and well deserves a wide circle of readers. It is unfortunate, however, that Mr. Leonard should give fresh circulation to the mistaken belief that war stimulates development, more particularly as in one of the examples cited by him, namely, aviation, war needs have been the main factor responsible for warping its whole development.

Electrical Laboratory Experiments—Theory and Practice:

being an Abridgement of "Experimental Electrical Engineering". By Prof. Vladimir Karapetoff. Arranged and Revised by Prof. Boyd C. Dennison. Pp. xii+487. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 20*s*. net.

KARAPETOFF's text on experimental electrical engineering had become so comprehensive that it became desirable for the production of the present abridgement for undergraduate purposes, but even so the number of experiments described—and these cover the 'heavy' or machine side only—are so varied and numerous that a normal undergraduate could expect to cover a fraction only. After all, it cannot be necessary that a student be taken through all the experiences possible; apart from training his hands, the purpose of laboratory work should be to give him faith in the theory that he obtains from books and lectures, supplemented by exercises, and he should be taught to depend on what he learns. Nevertheless, the present text would be invaluable in designing or improving laboratory courses. L. E. C. H.

Magic Squares of $(2n + 1)^2$ Cells

Avec sommaire: Les carrés magiques impairs. By M.-J. van Driel. Pp. 90. (London: Rider and Co., 1936.) 10*s*. 6*d*. net.

THE author of this volume has evidently devoted much research to the interesting study of magic squares, and though many results of his work were published in Amsterdam in 1931, it is pointed out that this book is not a mere translation of that work. New methods of composing magic squares of order 5 are given and, by a development of the uniform step method, constructions for squares of an order greater than 5 are deduced. Original practical rules are then enunciated for simple and pandiagonal squares of order $2n + 1$. Symmetrical and bordered squares are also considered.

The text is not easy to follow, although it contains much valuable information based upon sound mathematical principles and substantiated by many references to original work on the subject. The book concludes with a summary which is written in French.

The Flora of Krakatau

THE eruption of Krakatau, from May 20 to the end of August 1883, which killed the vegetation of the three islands of the Krakatau group and destroyed some two thirds of the island of Krakatau itself, was perhaps the most important volcanic outburst, from the point of view of the biologist, that has occurred in historic times. Its biological importance is, of course, due to the fact that Krakatau is now one of a group of four (formerly three) islands in the middle of the Sunda Strait, Krakatau itself being 40 km. distant from the nearest point of west Java, and the same distance from the nearest point, Varkenshoek, of south-eastern Sumatra. The nearest island to the group is the volcanic Sebesy Island, some 13 km. to the north, where the vegetation was not wholly destroyed. If, as has generally been accepted, the whole of the vegetation of the Krakatau islands was destroyed, then the study of the gradual recolonization recently published by Dr. W. M. Docters van Leeuwen is of unique interest and importance. Krakatau's historic eruption, however, is only one of a series each of which, could it have been studied, would have afforded invaluable information as to methods of plant distribution. From the geological evidence, there was originally a single volcanic island in the Straits about 2,000 m. high. This was destroyed, and the three main remaining portions are represented by Krakatau, Verlaten and Lang Islands, surrounding a deep circular sea basin. This eruption was followed by another violent one, and later, by the fusion of the two volcanoes Perbuatan and Danan, the historic island of Rakata or Krakatau, 9 km. long and 5 km. broad, was formed, two thirds of which were erupted and dispersed in 1883. Recently Anak Krakatau has been erupted.

Prof. Treub of Buitenzorg, it will be remembered, was the first botanist to visit Krakatau after the eruption in 1883. The earliest visitors to the island were Verbeek, two months, and Cotteau, the Frenchman, nine months after the eruption. Neither record the presence of any living plants, and Cotteau expressly states that he could not discern any vegetation on the island. It was the classic visit of Treub, nearly three years after the eruption, which focused attention on the problem of its recolonization, when he pointed out that the first colonizers of the volcanic ash and cinders were the blue-green Algæ, which formed a hygroscopic layer in which fern spores could germinate, and that under the conditions obtaining in a volcanic island such as Krakatau, ferns would necessarily precede the phanerogams. Of the plants recorded by Treub in 1886, eleven were ferns, eleven dicotyledons and four monocotyledons. He also found a few mosses; the fifteen flowering plants were mainly those which are usually found on sea-beaches.

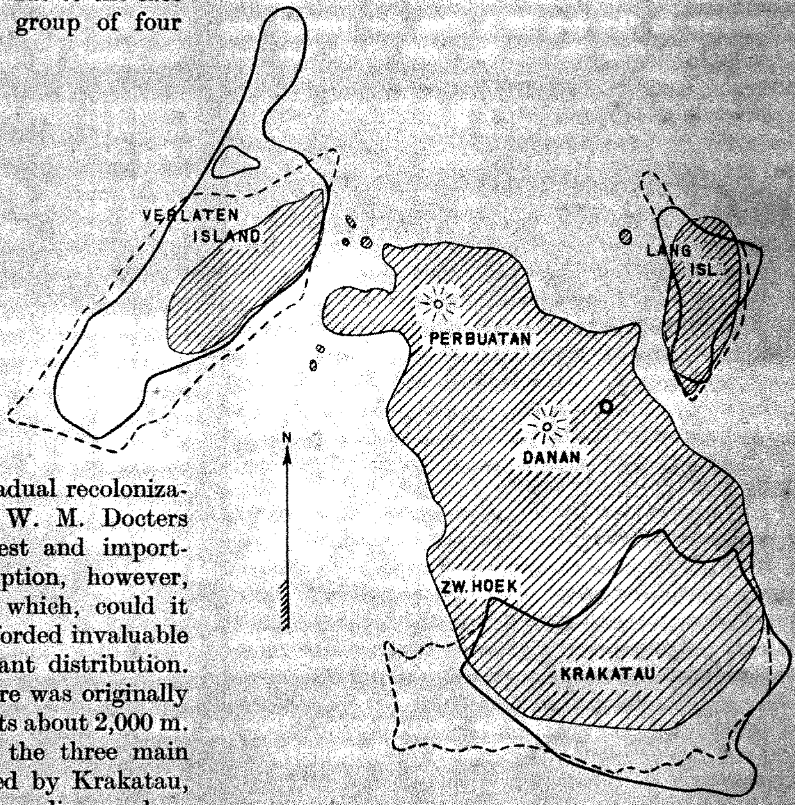

Fig. 1.
CHANGES IN FORMATION OF THE KRAKATAU GROUP.

Were these twenty-six plants found by Treub immigrants from land across the Straits, or were some of them survivors from buried seeds or from trunks or rhizomes, not wholly killed, which were exposed by the tropical rains washing away the overlying mass of ash and pumice thrown up by the eruption?

Thanks to the exhaustive labours of Dr. Docters van Leeuwen, we are now in a position to give a definite answer to this all-important question. In his masterly treatise on the island now before us, he has marshalled all the facts and discussed fully the evidence which has been produced for and against the total destruction of the vegetation of Krakatau by the eruption of 1883 with judicial fairness*.

The circumstances, unfortunately, do not permit of an *absolute* 'yes' or 'no', since three years elapsed before the fairly full investigation of the island by Treub was made, and even then owing to the extreme difficulties in getting up the deep fissures and among the waste of volcanic ejecta, it was possible to examine only a relatively small portion of the island. Verbeek's statement, however (see p. 18), with reference to his visit to Krakatau in October 1883, that the ground was then so hot that the coolies with their bare feet could not stand still and that steam was issuing from the bottom of the gaps cut out by the rain, makes it seem highly probable that all plant life, even that of seeds buried under the hot ashes and pumice, must have been destroyed. Verbeek concludes his letter to Docters van Leeuwen with praiseworthy caution: "I believe," he writes, "that this question can never be settled with absolute certainty, though I, myself, am inclined to assume that everything was dead".

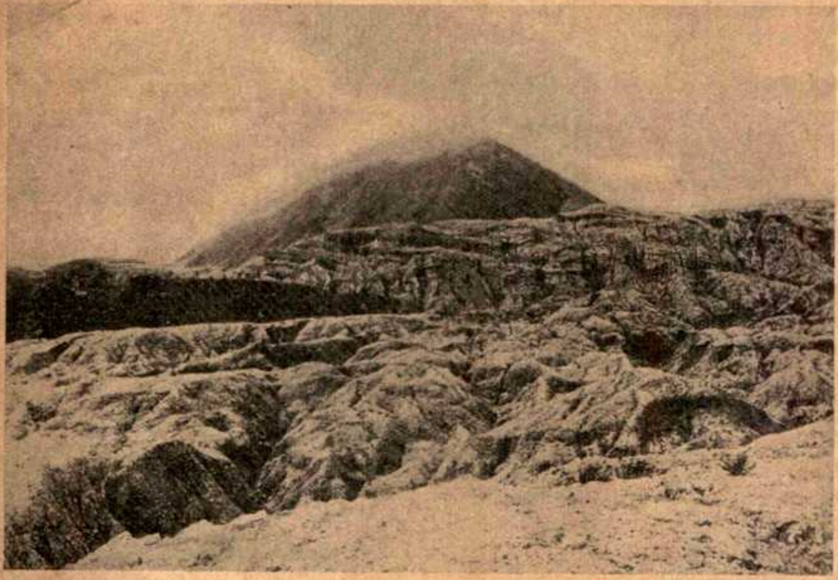

Fig. 2.
WEST SIDE OF ZWARTE HOEK, JUNE 20, 1886.
Photo by H. Busenbender.

Before the eruption, the islands were covered with dense tropical vegetation up to the top of Mount Rakata on Krakatau, and after the eruption there was nothing living to be seen, owing to the thick covering of ashes and pumice and the destructive effect of the hot gases, steam, etc. From the charred wood exposed by the washing away of the thick ash deposits, it seems clear that nothing in the way of stems or rhizomes could have survived. Buried seeds might have escaped destruction, had they been quickly exposed again by landslides or erosion, but the evidence for survival is very slight.

After all, Treub found only fifteen species of flowering plants three years after the eruption, and even if a few of these had grown from seeds which survived the eruption, their number is negligible compared with the 219 species which were recorded in 1934, all of which must have been brought to the islands by ocean currents, winds, birds or man.

Until the year 1908, no one appears to have questioned Treub's presumption of the complete sterilization of Krakatau. Penzig, who visited the island in 1897, Ernst in 1906 and Backer (on his first visit) in 1908, were all equally convinced.

The late Dr. J. P. Lotsy, writing in 1908, appears to have been the first to question the total destruction of the vegetation, on account of the finding of a large plant of *Cycas Rumphii* by Valeton in 1905, twenty-two years after the eruption! Based on the analogy of the growth of cycads in general, the objection might be a weighty one, but Dr. Docters van Leeuwen, on p. 346 in his detailed account of this plant, records how rapid is the growth of this species when young, and has shown by his own experiments that a plant of this *Cycas* can grow from seed to a height of more than 1 metre in the space of five years.

Other dissentient views are fully discussed and as fully rejected; it was not until the year 1929 that any serious challenge to the generally accepted opinion was brought forward. We have therefore to thank Mr. Backer (whose work was reviewed in NATURE, 125, 627; 1930), since it is not only owing to his expressed disbelief in the sterilization of Krakatau, but also on account of the aspersions he has cast on the work of Treub and the veracity and competence of previous investigators, including particularly Dr. Docters van Leeuwen, that we owe this volume, which will be the classic work of reference on the subject for all time and a vindication of Treub's fine pioneer investigations.

---

* Krakatau, 1883–1933. By W. M. Docters van Leeuwen. A: Botany. (Annales du Jardin Botanique de Buitenzorg, Vol. 46–47.) Pp. xii+506+37 plates. (Leiden: E. J. Brill, 1936.) By the courtesy of the publishers, several of the illustrations are here reproduced.

It is unnecessary here to go over again the various points raised by Backer, but it is good reading to follow Dr. Docters van Leeuwen's judicious handling of Backer's assumptions, some of which would have been quite reasonable had they had a shadow of evidence for their support.

Dr. Docters van Leeuwen has devoted a chapter (iv) of thirty pages to a review of the recolonization of other territories all over the world, and it seems clear that had any seeds remained viable after the eruption, such as those of *Ficus fistulosa*, *F. hispida*, *F. toxicaria*, *Macaranga Tanarius*, or even of *Cycas Rumphii*—the two *Ficus* first recorded in 1897, the rest in 1905—the seedlings would have been so tall in 1886 (several metres in the case of the first four, judging by observations made on their growth in Sumatra) that Treub could not have failed to have noticed them!

I fully agree therefore with Dr. Docters van Leeuwen, after carefully reading his able review of all the evidence, that not a single valid argument has been given that any part of the original vegetation of Krakatau was saved, and that the present plant covering of the islands must consist wholly of immigrants.

The author devotes eight extensive chapters to the visits of the various botanists to the islands between 1884 and 1932, one being concerned with the stay of J. Händl on Krakatau, from 1916 until 1921, and the fate of any plants he and his workpeople may have introduced. He then gives a complete list of the flora of the island and records the different dates when the various species—now numbering 271—were first observed. These are all dealt with in detail in the final chapters, which occupy 175 pages replete with valuable information. Chapter xvi deals with the means of transport by which the plants must have reached Krakatau—wind, sea, animals and man. Only the conclusions can be given here, but the discussion should be read in detail. Dr. Docters van Leeuwen feels justified in assuming that about 41 per cent of the plants now found in Krakatau (not counting the lower cryptogams), were transported by wind, 28 per cent were introduced by ocean currents, 25 per cent by animals, while not more than ten or fifteen plants, if as many, which may have been introduced by man, have survived.

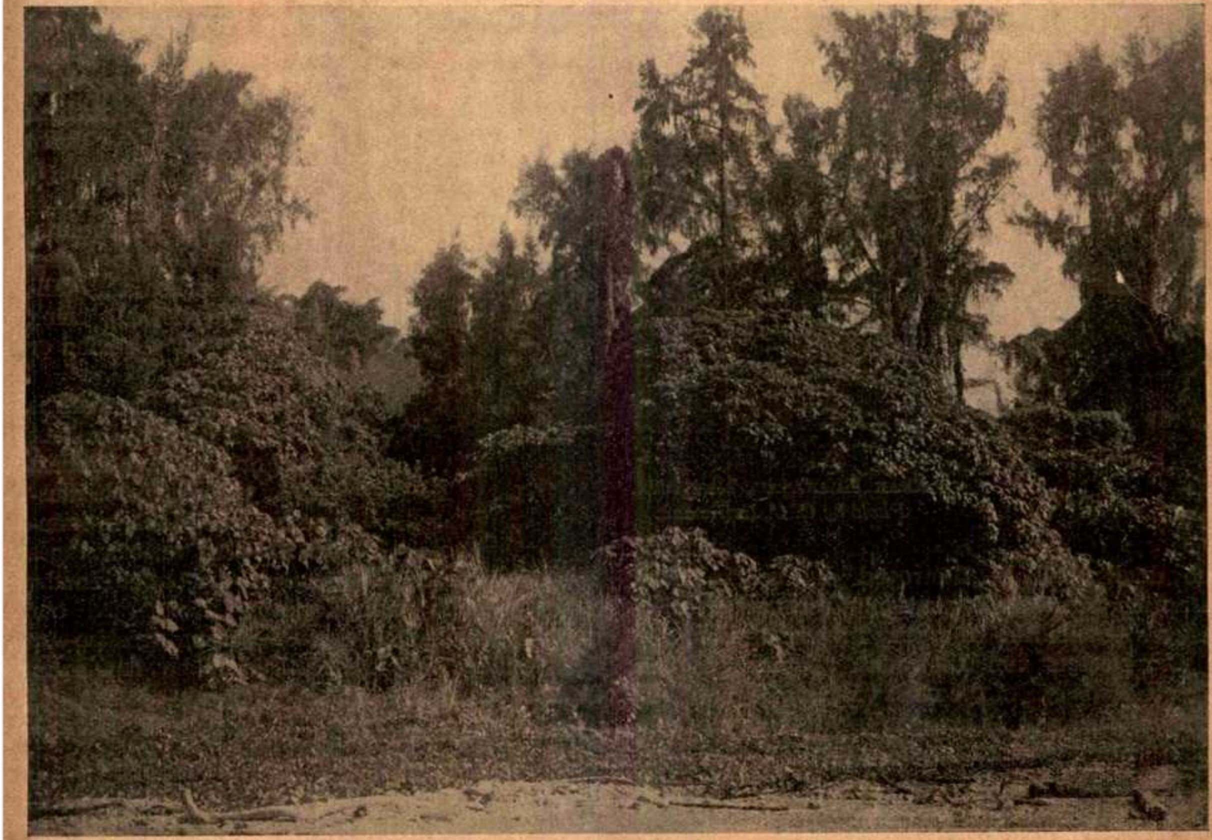

Fig. 3.
KRAKATAU, SOUTH-EAST SIDE, MAY 1928.

An interesting chapter (xviii) is devoted to the recently erupted island of Anak Krakatau, which first emerged above sea-level on January 26, 1928, and a list of the seeds and plants found on this 'baby' island by the author includes many coconuts, forty-one of which had germinated. These no doubt will be destroyed during the next eruption, but the colonization of this new creation affords possibilities of a very interesting study.

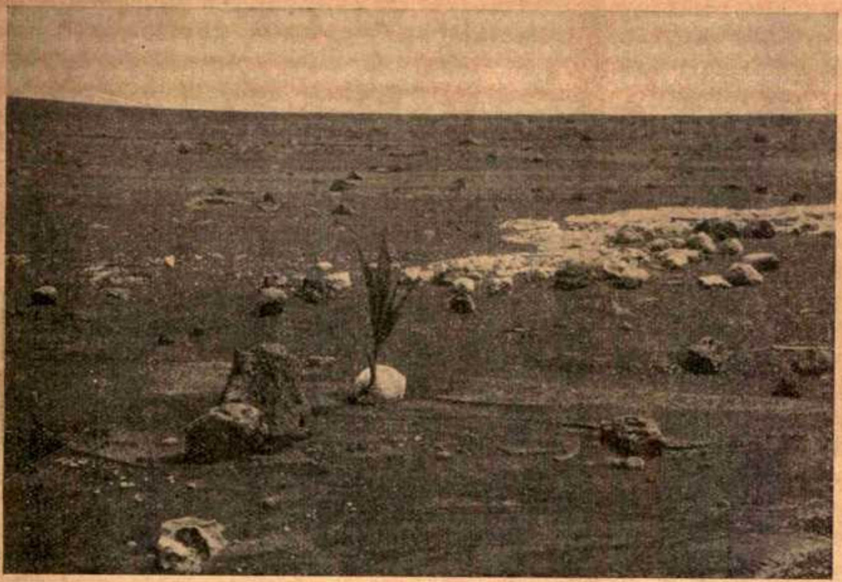

Fig. 4.
ANAK KRAKATAU, MAY 1932.
Photo by C. C. Reijnvaan.

Dr. Docters van Leeuwen's chapter (xxi) on *Zoocecidia* is one of the most valuable in the book, not only because he is a leading authority on the group, but also because these short-lived gall-producing insects and mites must have been destroyed by the eruption, so that all those now present on the island can only be immigrants.

No galls were found on the plants collected by Treub, though this does not prove that none had then arrived, but it is of interest that very few galls are known on the plants found by Treub on Krakatau in 1886. Dr. Docters van Leeuwen has collected no less than sixty galls on forty-four different plants on the islands. Since, then, it is inconceivable that these delicate insects can have survived the eruption, it is clear that the plants were the first immigrants, and when they had become established the gall-producers followed, being transported by the wind or ocean currents.

The value of the work is completed by the excellent bibliography and full index, and by the admirable illustrations, sixty-one in number, showing various stages in the development of the vegetation on the islands.

Dr. Docters van Leeuwen has earned our grateful thanks for this convincing treatise—so well written in English—which he has most fittingly dedicated to the memory of Melchior Treub.

ARTHUR W. HILL.

Prevention of Smoke and Dust Emission from Chimneys

THE weight of coal consumed annually in Great Britain is approximately 165 million tons, and of this only a small proportion is burned without smoke or grit being discharged into the atmosphere. It is, however, not possible to make even an approximate estimate of the extent to which the use of coal is responsible for atmospheric pollution and its attendant evils, on account of the wide differences which occur in the nature and quantity of smoke or grit produced by the combustion of unit weight of fuel. Both depend upon the type of coal used, the purpose for which it is burned and the skill employed in burning it, all of which vary from case to case.

When coal is burned on a domestic grate—and some 35 million tons are used annually for household purposes—the smoke produced consists of partially cracked tarry vapours formed by the distillation of a portion of the volatile matter in the coal. The quantity depends, of course, upon the type of grate and the nature of the fuel used. To burn soft bituminous coal smokelessly in an open fireplace is extremely difficult, but endeavours are being made to devise a suitable grate. Should they not be successful, it will be necessary, if smoke is to be avoided, either to abandon the open fireplace altogether, or to increase still further the use of smokeless fuel, such as low temperature coke, and gas or electricity.

The same type of smoke as that produced from domestic fireplaces may also be emitted from small industrial furnaces. In this case, however, there is no real difficulty in avoiding incomplete combustion. Its cause is usually either incorrect operation or the fact that the furnaces are being forced beyond their capacity. Reservations must be made in favour of certain metallurgical and ceramic processes requiring a reducing atmosphere, but even in these, improvements in the design of the furnace, care in the selection of the fuel, and scientific operation can often mitigate the nuisance. Generally speaking, therefore, the excessive emission of tarry vapours or soot from an industrial furnace is inexcusable. Nevertheless, many industrial furnaces are sources of a form of atmospheric pollution far more difficult to prevent than that due to incomplete combustion, namely, the dust and grit carried through the furnace by the draught.

In order to obtain sufficiently high rates of heat liberation in the space available, the air supplied for combustion may pass through the fuel bed at such a velocity that it will carry with it small solid particles of ash and unburnt or partially burnt fuel, as distinct from smoke. These may be relatively large, up to say ⅛ in. in diameter, and as, for economic reasons, the fuel used may be small in size and contain a considerable percentage of ash, the weight of solid material carried over may be high. In the case of large boilers, such as those found in power stations, the combustion chambers are so designed that the weight of carbon discharged in the flue gases is relatively small, but a large proportion of the ash in the coal is inevitably carried through the boiler. As the fuel often contains 10 per cent or more of ash, the weight of dust and grits discharged daily from a boiler burning several tons of coal per hour is appreciable.

During the last few years, an increasing number of the furnaces used in boilers and for metallurgical purposes have been fired with powdered coal. With this fuel most of the ash particles are less than 10 microns in diameter, with the result that, unless some form of dust-arresting apparatus is employed, most of the ash in the fuel will find its way up the chimney. This, more than any other isolated fact, has probably been the origin of the present increased interest in the prevention of dust emission.

The most obvious way of reducing the amount of dust leaving a furnace is to reduce the amount of ash supplied to it, that is, to use cleaned coal. It is gradually becoming realized that dirty coal is not necessarily cheap coal, and the use of cleaned coal is rapidly increasing. Nevertheless, it is not possible to clean boiler coal so as to reduce its ash content below a certain figure, say between 3 and 5 per cent on the average, so this method can provide only a partial cure.

A second method is to retain the ash in the furnace, and this is done to some extent in stoker-fired furnaces in which a large proportion of the ash fuses on the grate and is removed in lumps as clinker. The same method has been tried in certain pulverized fuel furnaces known as 'slag tap' furnaces, in which conditions are so arranged that the ash particles are caused to fuse into a pool at the base of the furnace, from which molten slag is run off at intervals. The arrangement is, however, not popular in Great Britain.

The remaining method, and the most generally used, is to remove as much dust as possible from the flue gases during their passage from the boiler to the chimney. For this purpose various types of dust extraction plant have been evolved, but their use is not so general as might be desired, mainly on account of expense.

In a few industrial processes the dust discharged has a commercial value and pays for its collection, but in most plants, including boiler furnaces, the dust produced is worthless and the cost of its collection is a complete loss, entailing not only capital, power and maintenance charges, but also the cost of disposing of the material caught.

Commercial dust extraction plants may be divided into two main groups, namely, dry and wet. The dry types include (*a*) those making use of gravity alone, (*b*) those using centrifugal force and (*c*) the electrostatic type; in these the collected material is removed in the form of a dry powder. In the wet types the dust is brought into contact with water sprays or films and is removed from the plant as a 'slurry'.

The simplest form of dry dust collector is a large empty chamber in which the solid particles settle out of the flue gases under the action of gravity. For such a chamber to be effective, a particle must be able to fall through the height of the chamber in less time than it takes the gas to travel through it. Now the rate of fall is proportional to the square of the radius of the particle, and the volume of flue gas leaving a boiler of only moderate size is very large; hence, in practice, an efficient settling chamber of reasonable dimensions is possible only with small boilers emitting large grits. Against this, the simple settling chamber has the great advantages that it requires no special fans or machinery and that no additional power costs are involved.

Many methods of reducing the size of settling chambers have been employed with varying success. Of these the most effective is the use of baffles or other devices which assist dust separation by causing the flue gases to undergo sudden changes of velocity and direction. The application of such devices is, however, limited by the fact that they increase the small pressure drop in the flue gases which constitutes the main advantage of the settling chamber. If fan power becomes necessary, more efficient forms of collector are available.

When a pressure drop of the order of about 2 in. water gauge or more is permissible, it is possible to use a form of separator in which gravity is replaced by centrifugal force. The simplest device of this type is the well-known cyclone, in which the flue gases enter a short cylinder tangentially and leave through a central axial opening. The dust is thrown out by centrifugal force and is collected in an inverted cone below the cylinder, being finally withdrawn through a suitable valve at the base.

The common cyclone has been subject to many modifications with the object of increasing its efficiency and decreasing the capital and power costs involved in its use. In addition, a great variety of other centrifugal devices have been evolved, for some of which high efficiencies are claimed, even with pulverized fuel dust. All these apparatus have the advantage of comparative low cost and simplicity, but all are subject to certain inherent limitations: they are more effective with large than with small particles, and their efficiency depends upon the flue gases being constrained to flow at a high velocity in a circle of small radius. As a result of these limitations, centrifugal separators may in practice be regarded as eminently suitable for arresting the relatively large grits associated with hand and mechanical stoker firing, but distinctly less satisfactory for dealing with the very fine dust from powdered fuel furnaces.

During recent years, particularly as a result of the growing use of powdered fuel, increasing attention has been given to a form of dry dust extractor which, although more costly than the types already mentioned, has the great advantage of being able to deal with very fine dust as well as with grits, namely, the electrostatic precipitator. In this device the dust-laden flue gases are caused to flow between two electrodes, one of which is charged to a high negative potential and the other earthed. As a result of ionic discharge between the electrodes, the dust particles become negatively charged and move towards the earthed electrodes to which they give up their charge, and upon which they are collected. They are then caused to fall into some form of hopper from which they are removed from the system.

The method has the advantages of low pressure drop, low maintenance charges, low power costs and, above all, its ability to give very high efficiencies with really fine dust particles. Against these there are the large space occupied by the plant and the use of high voltages. Its main drawback, however, is high capital cost.

All dry methods of cleaning flue gases have one fundamental disadvantage which is of major importance in the case of urban power stations, namely, the fact that no dry method of dust removal will also remove sulphur.

Before the problems associated with the contamination of the atmosphere by sulphur compounds reached their present importance, it was common practice to attempt to increase the efficiency of settling chambers and certain centrifugal separators by using sprays to wet the dust particles and so to increase their settling rate. The disadvantage of the method is that water does not readily adhere to fine dust, and in consequence the quantity of water required is very large indeed, involving not only the cost of providing and 'atomizing' the water but also the disposal of the 'slurry' leaving the plant—a task comparable in magnitude with that of the initial removal of the dust from the flue gases.

In spite of this, spray chambers are now being used on a very large scale, primarily to obtain sulphur removal and incidentally for dust removal. Thus in one large power station in Great Britain, one and a half million cubic feet of flue gases are scrubbed per minute in a system through which they take 30 seconds to pass, and 20 tons of water are pumped through sprays for every ton of coal burned. The slurry is dealt with partly by settling and partly by filtration through sand and rotary filters. The advantage of the system is that high efficiencies can be obtained with regard to both dust and sulphur removal, but against this must be balanced the high cost, the space and plant required and the necessity for large water supplies.

In some plants sprays are replaced wholly or in part by films of water in contact with metal surfaces, a system which still involves the use of large volumes of water and slurry treatment.

During the past few years, a new wet system has been evolved for the removal of dust and sulphur in places where large water supplies are not available. In this 'non-effluent' system, the gases are scrubbed by contact with special arrangements of wooden plates and grids, which are kept wetted by alkaline liquor continuously circulated through the plant. As with other wet systems, the solid matter suspended in the liquor has to be disposed of by settling and filtration, but the main problem, ingeniously overcome, is the prevention of scale formation in the scrubbing towers.

From this brief review it will be seen that adequate means are available for the prevention of excessive emission of dust and grit into the atmosphere. In the case of very large installations, public opinion has already compelled the use of admittedly expensive methods of dust removal, and there are signs that in the near future, whatever the cost, the demand made upon smaller plants will be more exacting than in the past. There are, however, also indications, both in patent specifications and in the technical press, that increased public interest in atmospheric pollution has given rise to increased experimental work upon its prevention, and it is reasonable to hope that by the time a more rigorous standard is adopted, its cost will not be too heavy a burden upon industry.

Obituary Notices

Mr. Thomas Crook, O.B.E.

A LIFE of strenuous and useful work with ripe experience terminated on January 6 when Thomas Crook, principal of the Mineral Resources Department of the Imperial Institute, London, died after an abdominal operation, at the early age of sixty years.

Crook was born at Burnley, in Lancashire, on January 12, 1876. On the examination results of the old Science and Art Department he gained in 1898 a Royal Exhibition to the Royal College of Science for Ireland, where he took the associateship (A.R.C.Sc.I.) in natural science in 1901. He then became assistant in geology to the late Prof. Grenville A. J. Cole. In 1905 he joined the Scientific Department of the Imperial Institute, and for six years (1919–25) he was chief of the Intelligence and Publications Section of the new Imperial Mineral Resources Bureau, which afterwards was incorporated with the Imperial Institute.

Thomas Crook, with his keenness for work and his balanced judgment, early gave promise of being a prominent scientific investigator; but in course of time, his energies became more and more devoted to economic problems in connexion with developing the mineral resources of the Empire. While in Dublin, he described with Grenville Cole rocks dredged from the Atlantic, and devised a method for the mechanical analysis of soils with the well-known Crook's elutriator. In London, under Sir Wyndham Dunstan, excellent mineralogical work was done, and papers were published on geikielite, carnotite, strüverite, ankerite and magnesite, on the electrostatic and electromagnetic separation of minerals, and on some curious optical properties of certain minerals. A paper with a philosophical bearing was "The Genetic Classification of Rocks and Ore Deposits", which several years later he expanded to form a book, "History of the Theory of Ore Deposits" (1933). Another excellent and useful book is his "Economic Mineralogy" (1921).

This promising scientific work gradually became eclipsed by a vast number of well-written abstracts and articles on the occurrence and possible uses of a great variety of mineral products, which appeared mostly in the *Bulletin of the Imperial Institute*, but without being keyed to an author's name (with the result that they were not always entered in bibliographies, and not easily quoted). With the foundation in 1919 of the Imperial Mineral Resources Bureau, a still more intensive period followed. Then were issued long series of useful pamphlets and books dealing with some fifty different minerals and ores, each complete in itself, and with several editions bringing the statistics up to date. Authoritative statistical volumes of the world's mineral production were also issued annually. Another useful volume, "Minerals of the Empire", was issued for the Wembley Exhibition in 1924. This good work was continued on Crook's return to the Imperial Institute in 1925. All these publications bear evidence of his influence.

Content in his work, Crook did not strive for honours; but some did come at the end of the chapter. He was made O.B.E. in 1936. In November last he was elected a vice-president of the Mineralogical Society; and in December the honorary degree of B.Sc. was conferred on him by the National University of Ireland.

L. J. S.

Dr. E. E. Prince

DR. EDWARD ERNEST PRINCE died at his residence in Ottawa, Canada, on October 10, at the age of seventy-eight years. A native of Leeds, he graduated from the University of St. Andrews, and taught in the University of Edinburgh and (as professor of biology) at the Royal College of Medicine, Glasgow. He was one of the group studying the development of fishes under Prof. W. C. McIntosh at the St. Andrews Marine Laboratory. His publications in this field gave him recognition as a fishery specialist, and as such he investigated the fisheries on the east coast of England and the west coast of Ireland.

In 1892 Dr. Prince was appointed commissioner of fisheries for Canada, which position he held until his retirement from active life in 1925. Being responsible for the application of science to fishery problems, he urged in 1894 the establishment in Canada of a marine scientific station, and the support of the Royal Society of Canada and of the British Association at its Toronto meeting in 1896 led to the Canadian Parliament voting the necessary funds in 1898. He was made director of the new station, which operated with a board of university men to manage it and was located on the Atlantic coast. When a Great Lakes station and a Pacific station were afterwards developed, he continued to guide the work as chairman of the modified Board (incorporated in 1912 as the Biological Board of Canada), retaining this position until 1921 and remaining a member of the Board until his death.

Dr. Prince played a leading part on various fishery commissions in Canada, and with Dr. D. Starr Jordan formed the International Fishery Commission, established by treaty in 1908, which prepared common regulations for the fisheries in waters contiguous to Canada and the United States.

Dr. Prince was a keen naturalist and intensely interested in people. By charm of manner and breadth of interests he exercised a wide influence in a multiplicity of personal contacts throughout Canada and elsewhere. He was the author of more than fifty papers, nearly all on fishery subjects, and initiated or stimulated a large part of the investigations of Canadian waters, effectively applying to the first stage of fisheries research in Canada the knowledge and experience he had developed in Great Britain.

A. G. H.

Mr. G. P. V. Aylmer

We regret to record the death of Mr. Gerald Percy Vivian Aylmer, African traveller and explorer, which took place on December 20 at Newcastle-on-Tyne in his eightieth year.

Mr. Percy Aylmer, as he was generally known, was born in 1857 and educated at Eton and Trinity College, Cambridge. Notwithstanding the fact that as a result of a fall in the hunting field at Cambridge one leg was permanently deformed, Mr. Aylmer on leaving the University entered on a life of travel and strenuous adventure. In 1881, after taking a course of study in astronomy, he went to the Sudan with F. L. and William D. James and E. Lort-Phillips. The party entered the then unknown Basé country and mapped this region for the first time. Until then, it is said, no white man who had attempted to enter this country had ever returned. In 1884 the same party succeeded, where Burton, Speke and others had failed, in crossing the Horn of Africa and reaching the Webbe Sinbeli River. Here again uncharted lands were traversed; parts of Somaliland, including Wal-Wal, were then mapped for the first time. Observations on the natural history and natives of the country were noted in Aylmer's diaries, it is stated by Sir Alfred Pease in a communication to *The Times* of January 1; but unfortunately these have never been published.

We regret to announce the following deaths:

Prof. J. A. MacWilliam, F.R.S., emeritus professor of physiology in the University of Aberdeen, on January 13, aged seventy-nine years.

Dr. R. J. Tillyard, F.R.S., formerly chief Commonwealth entomologist in Australia, on January 13, aged fifty-five years.

Dr. T. B. Wagner, consulting chemist on foods and chemical engineer, president of the American Institute of Chemical Engineers in 1913, and vice-president of the Society of Chemical Industry (London) in 1908, on November 12, aged sixty-seven years.

Dr. Theodor Wiegand, president of the Archæological Institute of Berlin and director of excavations at Pergamon, aged seventy-two years.

News and Views

International Congress of Genetics and the U.S.S.R.

The next International Congress of Genetics was to have been held at Moscow in August next, the preparations for it being in the hands of Russian geneticists. A wireless message from Moscow to the *New York Times*, which was published in *Science* of December 18, stated that the Congress had been cancelled by the Soviet Government; that genetics had been attacked as of no practical value by T. D. Lysenko, who is known for his work in the vernalization of wheat and other crops; that Prof. N. I. Vavilov, the distinguished head of the plant-breeding services in the U.S.S.R., had been arrested; and that Prof. S. G. Levit, who is director of the Maxim Gorky Medico-Genetical Institute and was general secretary of the Organization Committee for the International Congress of Genetics, had been heavily attacked in the Communist party press for allowing a member of his staff to publish a paper in which it is concluded that the Buryats of Siberia have a mental age of twelve years. Prof. Vavilov has since sent to the *New York Times* a message, a copy of which has been sent to us by the Soviet Union Year Book Press Service, denying the story of his arrest and pointing out the large growth which has taken place in the Institute of Plant Breeding under his direction during the Soviet regime. According to a report circulated by Science Service, of Washington, D.C., Prof. H. B. Ward, permanent secretary of the American Association, has received a message from the U.S.S.R. indicating that the Congress of Genetics has been postponed but not cancelled. As the titles of papers for the Congress were to have been sent in soon, it is clear that a more definite announcement regarding the postponement is desirable, since many geneticists were already making arrangements to attend. These Congresses have been held every five years, the last being at Ithaca, New York, in 1932 No adequate grounds for a postponement have yet appeared.

Prof. N. I. Vavilov

PROF. N. I. VAVILOV, whose work is mentioned above, was a pupil of Bateson at the John Innes Horticultural Institution, London, in 1913 and 1914. Profiting by the unexampled opportunities afforded by the Soviet Government, he began in 1919 to study the natural variation of the ancestral species of cultivated plants. His special method was to use the geographical distribution of particular gene variations in determining the centre of their diversity, which he presumed to be the site of their origin. He applied this method to all the principal crop plants, leading expeditions to all parts of the world. This enabled him to infer the centres of origin of these plants. The most interesting example of this method concerns the wheats. The cultivated forms were already known to fall into two inter-sterile groups, the tetraploids like *T. durum*, *T. turgidum*, *T. polonicum*, and the hexaploids like *T. vulgare* and *T. compactum* Vavilov found that the hexaploids had arisen from a Central Asiatic centre, while the tetraploids had arisen from an entirely different centre in North Africa, hence the association of the two groups of wheat with different lines of human cultural development.

THE precise value of Prof. Vavilov's methods and the importance of his "Law of Homologous Series in Variation", and his principles of regional selection, are only beginning to be appreciated, but his published work undoubtedly represents the most important systematic attempt to study natural variation in plants since De Candolle and Darwin. Since 1921, Vavilov has been director of the Institute of Plant Industry. Under his control, this organization has come to embrace stations distributed all over the Soviet Union. Vavilov has used his centralized authority to secure a co-ordination of genetics, cytology, physiology and taxonomy, in which more than two thousand trained workers are engaged in problems of the efficient utilization of plants in the national economy. The work of acclimatization and hybridization carried out by the Institute bears witness to the success of his work, a success which is due to the combination of an enlightened method of inquiry with an industry, enthusiasm and organizing capacity suited to the heavy responsibilities given him by the Soviet Government.

International Geological Congress, 1937

IN spite of the difficulties which the International Congress of Genetics appears to be meeting, Soviet geologists are busy preparing for the eighteenth International Geological Congress, of which the opening plenary meeting will be held in Moscow on July 21. The session will close on July 29. Excursions, both prior to and following the Congress, are being arranged for delegates and their families. Pre-Congress tours, beginning on July 1, include the following: (*A* 1) Karelia and the Kola Peninsula: Pre-Cambrian; igneous complexes; ore deposits; (*A* 2) Ukraine and Crimea: Pre-Cambrian; Donets Coal Basin; Crimean stratigraphy and tectonics; (*A* 3) Volga: stratigraphy of the East European U.S.S.R.; Caspian depression; salt domes; engineering problems; (*A* 4) Caucasus: stratigraphy; tectonics; igneous activity and ore deposits; (*A* 5) South Urals, Kazan and Donets Basin: stratigraphy and palæontology of the western slope of the Urals. The longer August excursions, the first two of which will occupy forty days, are as follows: (*C* 1) Urals, Caspian, Caucasus: the principal oil deposits of the U.S.S.R.; (*C* 2) Siberia: Caledonian, Variscan and Alpine tectonics; Palæozoic and Mesozoic stratigraphy and associated coal and iron deposits; (*C* 3) Novaya Zemblya: stratigraphy and tectonics; Caledonian granites and mineralization; (*C* 4) Urals: gabbro-peridotite and alkali complexes; mineral deposits of great variety. Full details and conditions of membership are given in the Third Circular, issued by the Organization Committee, copies of which may be obtained from the General Secretary, Moscow 17, Bolshaya Ordynka, 32. All arrangements for travelling, hotel accommodation, etc., are in the hands of Intourist, Ltd., Bush House, Aldwych, London, W.C.2.

Races in the British Isles

IT is generally considered more or less a fixed point in discussion of the racial history of the British Isles that a fundamental element in the population, which appears at least as early as the long barrow, is of Mediterranean origin. It will, therefore, come as a surprise to many to find that arguments subversive of this view have been put forward recently by Dr. G. B. Morant (*J. Roy. Anthrop. Inst.*, **66**, Pt. 1) in an analysis of the material upon which Dr. Cecil P. Martin based his study of the racial composition of the Irish people in "Prehistoric Man in Ireland" (London: Macmillan and Co., Ltd., 1935). Dr. Martin's conclusions pointed to a virtual identity of racial history in Ireland and Britain up to the intrusion of the Romans and Saxons in Britain. Ireland, however, on the whole was said to have a larger Iberian element and a smaller Nordic element than Britain. Dr. Morant, after a statistical analysis of the modern Irish material, has arrived at the conclusion that the modern Irish and the British Iron Age population are so similar that they might be samples from the same material, while the latter bear the same relation to the population of the Whitechapel plague pit of the seventeenth century. The Anglo-Saxon is slightly removed; but the modern English and the modern Irish might well be considered variants of one race.

ON this argument, it would, therefore, appear that the Iron Age population absorbed the Anglo-Saxon type. Further, this race, with which Dr. Morant would class the British Neolithic, on comparison with Continental types, emerges as essentially Nordic. It is comparable with the prehistoric Scandinavian, the Reihengraber people, the Merovingians of northern France, and the Belgian Franks—all Nordics. Dr. Morant justifies the inclusion of the British Neolithic in this group on the evidence of stature and head-measurement, pointing out that the extreme length characteristic of the Nordic skull, in which it exceeds any of the dolichocephalic Mediterranean skulls, is also a character of the British neolithic skull. He argues, therefore, that there is no evidence in skeletal remains for the early presence of a Mediterranean element in Neolithic Britain, but that this has been inferred on cultural evidence only. It will be noted that the important character of pigmentation does not enter into the argument; but as has been pointed out on more than one occasion, the argument from pigmentation in the classification of the prehistoric races of Europe rests solely on inference from modern distributions, until in the historic succession we come to the evidence reported in the classical writers.

Colonial Medical Reports

MAJOR P. GRANVILLE EDGE read a paper before the Royal Statistical Society on January 19 entitled "The Demography of British Colonial Possessions", in which some of the outstanding details to be found in Colonial medical reports were summarized. It was pointed out that the British Colonies comprise upwards of fifty distinct Governments, with territories exceeding an area of two million square miles, of which more than nine-tenths lies wholly within the tropics, inhabited by a bewildering medley of races, religions, languages and customs. The bulk of the people of British tropical Africa are native-born Africans, but in British Malaya the Chinese outnumber the indigenous Malays, and in the British West Indies no traces of the original Carib inhabitants survive, the present population being composed of descendants of African slaves, East Indians, Europeans and other inter-racial mixtures. The Colonial medical reports contain records of population, births, and deaths, so far as these are known, and in addition survey the records of sickness in the Colonies with the view of discovering and removing the predisposing causes of various diseases. The incidence in different parts of the world of such diseases as malaria, helminthiasis, venereal affections, dysentery, sleeping sickness and tuberculosis were discussed by Major Granville, and the difficulties connected therewith commented upon. The public health services, wherever located, may be regarded as fighting organizations engaged in combating insanitary conditions, in raising defences against the invasions of disease, and in attempting to stave off the approaches of death. Without these services detailed sanitary knowledge cannot be acquired, and without such knowledge commercial and other development of the Colonial Empire must be precarious and costly in the face of unrealized menaces to life and health.

Magnesium Alloys for Aircraft

As the standards of aircraft performance are raised, possible saving of weight is becoming of ever greater importance, so that more and more interest is being taken by aircraft constructors in metals lighter than aluminium. On January 14, Dr. C. H. Desch, superintendent of the Metallurgical Department of the National Physical Laboratory, discussed, before the Royal Aeronautical Society, recent work on magnesium and other light alloys, much of which has been carried out at the National Physical Laboratory. Magnesium is too weak a metal to be used in the unalloyed state, and the metals which may be added to it to produce strong alloys are limited in number. In fact, taking all the factors into account, only aluminium and cadmium are suitable for alloying in comparatively large quantities, although calcium, cerium, nickel, cobalt and manganese have proved useful in small quantities. To those who have only known magnesium in the form of ribbon or powder for use in flashlights, it is rather surprising to find that magnesium alloys are remarkably easy to cast. This comes about, Dr. Desch said, from the fact that molten magnesium has very little power of dissolving gases, so that magnesium alloys do not suffer from porosity caused by the liberation of gases at the moment of freezing. It is necessary to use a suitable flux and a protective atmosphere during pouring. These conditions are now well understood, and no difficulties are experienced in the foundry. In annealing processes similar protection is necessary, and the special technique adopted has resulted in making a magnesium alloy foundry a remarkably clean and inoffensive place. Exhaustive search at the National Physical Laboratory for magnesium alloys capable of age-hardening has suggested that those containing silver are the most promising. The fact that silver is relatively costly is of little importance, since in the articles of the type produced the cost of manufacture is much greater than that of the material used.

Afforestation in the Lake District

AN interesting pamphlet has been issued by the Forestry Commissioners entitled "Afforestation in the Lake District" (London: H.M. Stationery Office, 1936). The pamphlet embodies the report by the Joint Informal Committee of the Forestry Commission and the Council for the Preservation of Rural England which was set up early in 1935. The Committee commenced its task with the recognition that large-scale afforestation and the preservation of areas of typical natural beauty are both necessary on national grounds, and that the land available for both purposes is limited. This does not entirely represent the actual position of affairs. For the public in some cases in the past have not only been against new afforestation work, but also have declaimed at old woods, such as are to be found in some of the enclosures in the New Forest, for example, being touched; in spite of the fact that it is evident that the old trees cannot last for ever. Towards the end of 1935, the Commissioners acquired an estate of 7,000 acres in the valley of the River Esk and the adjacent valley of Duddon, and prepared to plant. Objections were made by the public to the planting of conifers in the two valleys, especially in Upper Eskdale. It was agreed that some 440 acres of plantation land in Upper Eskdale should be omitted from the planting scheme, the Commissioners undertaking to pay special attention to amenity in afforesting the remainder of the plantable ground. The total area of the estate which will be ultimately planted is less than 2,000 acres of the 7,000 acres purchased. It has become evident that afforestation in the Lake District offers considerable difficulties, as a countryside can be completely changed by stretches of woods, and especially coniferous woods. With this object in view, the Joint Committee has recommended that a central block of some three hundred square miles in extent should be excluded from afforestation work.

British Films and the Cinema

THE Committee appointed by the Board of Trade to consider the position of British films in view of the approaching expiry of the Cinematograph Films Act, 1927, has now issued its report (Cmd. 5320 London: H.M. Stationery Office. 9*d*. net) It finds that in some important respects the situation is still the same as in 1926. The much greater home market available for United States films, which is represented by some 11,500 picture-houses and a seating capacity of about 10,000,000, as against 4,300 cinemas in Britain and a seating capacity, including that of the Dominions, of less than 6,000,000, offers a security encouraging a flow of capital to the American industry which finds no parallel here. The United States accordingly occupies a commanding position, contributing all but 25 per cent of the films shown in Great Britain, and the Committee was unanimous in its decision that the quota system should be continued and the quotas, under certain conditions, increased. The detailed proposals of the report are accordingly designed to deal with admitted flaws in the present system rather than to modify its principles. A quality test is proposed to restrict the deplorable output of bad films made simply to satisfy quota requirements An increase in the penalty for blind booking, which is to apply to renters and not to exhibitors, removal of restrictions on advance booking but prohibition of block booking, and the application of the quota system to short as well as to long films are among other recommendations of the Committee It is suggested that long and short films should be judged by different standards, and stress is laid upon the value of the short film as an opportunity of experimenting with new ideas within reasonably safe financial limits. The ultimate aim of the measures proposed is to reach a quota of fifty per cent in the next ten years, and to give effect to its recommendations and administer the provisions of the new legislation required, the report recommends the constitution of a Film Commission of members entirely independent of any professional or financial interest in the industry.

Architectural Lighting

A PAPER by R. O. Sutherland published in *Light and Lighting* of December gives a history of the progress made in architectural lighting during the last ten years. He states that this kind of lighting received great inspiration from the French Colonial Exhibition in 1925. As a result of the illumination shown at this festival, ornamental features in the form of tiles and richly decorated panels in moulded glass were popularized in buildings, especially those used for catering and entertainment purposes. The floral character of this lighting soon gave way to a more restrained treatment. Plain sheet opal glazing was largely substituted for moulded glass. This made it economical to have large areas of lighted panels. Once the idea of converting an architectural element into a lighting feature was established, it rapidly became a typical method of architectural lighting technique. A photograph of the lighting of the Egyptian Hall in the London Mansion House, and of the lighting in the library of the University of Cambridge, show how the architectural treatment is emphasized in a simple and dignified way by the illumination. To Londoners and visitors to London the lighting of some of the escalators on the underground railways is of interest. The barrel ceiling is lighted from standards placed at 8-foot intervals, each containing a 100-watt lamp in a suitable reflector. The illumination is ample for the needs of the traveller, and is sufficient for the vault sides to be used as advertisement space. In the lighting of the gallery of the Shakespeare Theatre at Stratford-on-Avon, the acoustic panels at the back of the auditorium are also utilized as light reflectors.

Timber for Wood-Turning

AN interesting, and, from the point of view of encouraging small local industries in the countryside, practical report has been issued by the Forestry Commission (H.M. Stationery Office, 1936), entitled "On the Demand for Timber in Wood-Turning in Great Britain". The investigation was carried out in 1935, when 438 firms were visited, all but 14·8 per cent being wood-turners. The information upon which the report is based comes therefore from 373 firms ranging from single-handed turners who have one room or a small shed fitted up as a workshop, to mass-production factories with a hundred or more automatic or semi-automatic machines. Some of these latter specialize in the production of a single commodity, such as heels for shoes, legs for chairs, bobbins for textile mills, rollers for mangles, the manufacture of tool handles, or bungs for beer-casks; others are general turners, fabricating a wide variety of products. The majority of the firms are turners only The last census returned 56,930 persons, including pattern makers (the latter being chiefly of wood), as employed in the United Kingdom in wood-turning It is difficult to obtain figures of the actual consumption of wood in this industry; but, from information supplied, approximately two hundred firms are using 6,000,000 cubic feet of timber in wood-turning annually, of which about 53 per cent is home-grown and 47 per cent imported.

Agricultural Meteorology

MR. J. W. HOPKINS has recently published a paper, entitled "Agricultural Meteorology: Some

Characteristics of Precipitation in Saskatchewan and Alberta", in which it is apparent that the author's investigations and their results may have a wider application than the merely agricultural (*Canadian J. Res.*, 14, No. 9, Sept. 1936). In previous agricultural meteorological investigations, Mr. Hopkins demonstrated statistically significant correlations between annual variations in rainfall and temperature, and the yield and nitrogen content of wheat crops grown in central and southern Saskatchewan and Alberta. In the present paper, the author gives the results of a study complementary to the previous one, dealing with some average characteristics of the seasonal precipitation in these districts, and also analysing the fluctuations which past experience has shown to occur from year to year in the precipitation at a given place, and from place to place in the same district during a given year. The investigations appear to be based on observations carried on between 1898 and 1934, the stations being Edmonton, Calgary, Battleford and Swift Current. "In spite of irregularities, to be expected in the limited sample of years available," says the author, "the frequency of distribution of seasonal precipitation at the stations showed no gross asymmetry, seasons with precipitation in the vicinity of the average being on the whole more numerous." The average (1916–32) percentage of days on which rain fell showed a distinct seasonal trend during spring and summer, being lowest in April and highest in June. Similar variation was noted in the average amount of rain per rainy day, which was lowest in April and highest in June and July. It would be of interest if in future observations some data could be collected on the subject of the possible influence of the forests on the atmospherical moisture content in these regions.

Plant Pathology in Devon and Cornwall

THE twelfth annual report of the Department of Plant Pathology at the Seale-Hayne Agricultural College, Newton Abbott, Devon, considers the pests and diseases of plants from an essentially local aspect, which should be much appreciated by growers in Devon and Cornwall. Mr. L. N. Staniland, the advisory entomologist, contributes a general section upon the more common pests of farm and garden. He has made a special study of eelworm troubles. Methods of combating this pest are discussed at considerable length, and a thorough revaluation of the usual hot-water treatment has been made. It has been found that although eelworms are killed by seventeen minutes exposure to a temperature of 110° F., the technique of commercial treatment varies greatly. The usual period of three hours heating is shown to be inadequate in some cases, and various recommendations as to improved methods are made. Mr. A. Beaumont, the advisory mycologist, has made a further detailed study of the relation of potato blight to the weather of Devon, and has separate articles on "Tulip Fire and the Weather", "Snapdragon Rust; Trials of Resistant Varieties", and "Apple and Pear Fruit-rotting Fungi".

Vital Statistics for England and Wales for 1934

THE text volume of the Registrar-General's Statistical Review of England and Wales for 1934, recently issued, contains the official commentary on the two volumes of vital statistics already published (London: H.M. Stationery Office. 3*s*. 6*d*. net). The report deals with the statistics of births, deaths and marriages registered in 1934, estimates of population, and other matters. The estimated population of England and Wales in the middle of 1934 was 40,467,000 persons, of whom 19,412,000 were males and 21,055,000 females. The total is 117,000, or 0·29 per cent greater than the estimate for the previous year, and 515,000 or 1·3 per cent greater than the population at the census of 1931. The average ages of the estimated population, which are gradually increasing, are 32·4 years for males and 34·2 for females. In addition to reviewing the mortality from various causes, the report also contains several studies of mortality. One of these deals with the handicaps suffered by the winter-born compared with the summer-born child, and another with the mortality rate from pregnancy and child-bearing for the wives of men in various social groups.

Fall in French Birth-Rate

THE annual number of births in France reached its maximum towards the end of the Second Empire, when it was so high as 1,034,000 in 1868. In 1934 it had fallen to 677,000 and in 1935 to about 650,000, of which nearly 50,000 were the children of foreigners. The birth-rate has therefore diminished by 384,000 or nearly a third, although the population has increased since 1868 by three million immigrants or naturalized persons, which has resulted in increasing the population from 38 to 48 million inhabitants. During the period 1900–35, the birth-rate has decreased by nearly 100,000. The number of births per marriage has decreased even more rapidly. In 1800 the average number of births in France was 4·5 per marriage, at the end of last century it was 3, and to-day only 2·2, or a diminution of about fifty per cent.

The Value of Experiments on Animals

THE autumn issue of the *Fight against Disease* (24, No. 4), the quarterly journal of the Research Defence Society, contains extracts from the evidence given by Lord Justice Fletcher Moulton before the Royal Commission on Vivisection, 1906–8. The considered opinion of Lord Moulton, whose scientific knowledge and clarity of thought must have materially assisted the Commission in forming an opinion upon the anti-vivisection controversy, should help those who have to address meetings on the question, or have to deal with anti-vivisection propaganda.

Physics in Industry

AT the meeting at the end of October commemorating the fifth anniversary of the founding of the American Institute of Physics, the replies of fifty leading industrial physicists to the question: what training is best for the scientific worker who wishes to enter industry, were summarized by Dr. Oplin, director of research at Kendall Mills, Boston. His summary has been taken up by Science Service, Washington, D C., and circulated His principal conclusions are: "Industries need physicists trained in the fields of optics, magnetism and acoustics", and "too little emphasis is placed on these fields in academic training" as "the best known scientists are working on the problems of cosmic rays, atomic disintegration and transmutation" and "students naturally look up to them for guidance". "Some training in engineering courses is advocated for future industrial physicists. Industry finds it better and easier to use a student trained adequately in physics and have him in the plant attain his additional engineering knowledge than to try to give the engineering student the additional knowledge of physics".

R.R.S. *Discovery II* Survey Party

CONSIDERABLE concern was caused by the announcement on January 18 from the commanding officer of the R.R.S *Discovery II*, that a survey party which had been landed on King George Island, South Shetlands, was missing Early on the following day, however, the reassuring message was received that the party had been located and had returned to the ship The Discovery Committee states that the party consisted of: Lieut. R. Walker, R N.R., chief officer; Dr J. R. Strong, ship's surgeon; Dr F. D. Ommanney, scientific officer; Mr. R. G. Gourlay, third engineer; Mr J. Matheson, boatswain's mate, and Mr J. Dobson, A B.

Bureau of Human Heredity

ONE activity contemplated in setting up the Bureau for Human Heredity is the organization of information service for research workers in the subject The value of such a plan has been demonstrated in the information service already established for workers on *Drosophila*, etc. Workers are requested to address to the Bureau a short paragraph describing the work on which they are engaged These notices will be multiplied and circulated to all those co-operating In the first instance, this bulletin will be issued every twelve months. Later supplementary bulletins will be issued more frequently. Those using this service are asked to subscribe 5*s*. Communications should be addressed to the Hon. General Secretary, Bureau of Human Heredity, 115 Gower Street, London, W.C 1

Federal Council on Scientific Management

AN important step forward in the co-ordination of the varied activities of the many societies connected in some way or other with the several phases of scientific management was taken on January 12, when a British Management Council was formed. After the highly successful sixth International Congress for Scientific Management, held in London during July 1935, a committee was set up under the chairmanship of Dr E. F Armstrong both to take all necessary action to ensure the proper representation of Great Britain at the next Congress, to take place in the United States in 1938, and to examine the factors involved in the formation of a national scientific management organization A scheme of federation has been produced by this committee, and after discussion has met with provisional acceptance from the greater number of the associations concerned, numbering some thirty in all. The objects of the new Federal Council are: "To ascertain and represent both nationally and internationally the views of those bodies concerned in Management in Great Britain, and in particular as its immediate object to enter into relations and to co-operate with similar bodies in other countries, and to act as the representative of its Constituent Members in International Congresses and other activities concerned with Management." Lord Leverhulme has been elected as its first chairman, Dr E F Armstrong as vice-chairman, Mr. G. R. Freeman as treasurer, and Mr. U. Baliol Scott as secretary. The new body is assured of the support and co-operation of the Federation of British Industries. It has an important function to fill and may be expected in time to exert a pronounced influence on the development of the functional management movement in Great Britain.

Botanical Society of America

AT its thirty-first annual meeting at Atlantic City, New Jersey on December 20–31, the Botanical Society of America elected the following botanists to be corresponding members: Dr. N. I Vavilov, director of the State Institute for Experimental Agronomy, Leningrad; Dr. Agnes Arber, sometime fellow of Newnham College, Cambridge; and Dr. Lorenzo R. Parodi, professor of botany in the University of Buenos Aires The following officers of the Society for 1937 were also elected: *President*, Prof Edmund W. Sinnott, Barnard College, Columbia University, New York City; *Vice-President*, Prof. Loren C Petry, Cornell University, Ithaca, N.Y.; *Secretary*, Prof George S. Avery, jun., Connecticut College, New London, Conn: *Treasurer*, Dr. F E. Denny, Boyce Thompson Institute for Plant Research, Yonkers, N.Y. A new Section for Paleobotany was also organized with the following officers: *Chairman*, Prof. A C. Noé, University of Chicago; *Secretary*, W. C. Darrah, Harvard University

International Congress of Agriculture

THE seventeenth International Congress of Agriculture will be held at The Hague on June 16–23, 1937, under the patronage of the Queen of the Netherlands. The work of the Congress is divided among eight sections. Three are economic in character, and at The Hague will discuss the means which have been taken to deal with the depression in the agriculture of the Netherlands, the organization of the world butter market, the provision of credit to agriculture, the relation between State planning and agricultural co-operation, the effect on agriculture of the development of artificial wools, cottons and other products. Sections dealing with the technical and scientific aspects of agriculture will discuss the vernalization of crops, a limitation in the varieties of plants in cultivation and the protection of producers of selected seeds, artificial fertilization in the improvement of livestock, animal nutrition and other subjects. Social and educational questions will include the teaching of agricultural economics, broadcasting in the service of agriculture and health and hygiene in the rural home, a subject to which the National Federation of Women's Institutes (England) will make the principal contribution. Further particulars may be obtained from the Secretary, British Corresponding Committee, International Congress of Agriculture, 10 Doughty Street, London, W.C.1.

An International Exhibition of Photography

UNDER the chairmanship of Gustave Fassin, of the Bausch and Lomb Scientific Bureau, Rochester, New York, a committee has been appointed to secure and arrange exhibits for the International Exhibition of Applied and Scientific Photography to be held in the Rundell Memorial Building at Rochester, New York, in March, under the auspices of the local section of the Photographic Society of America. This new and beautiful civic building has exceptional facilities for showing both pictures and apparatus. Men of science working in any of the following fields are invited to send exhibits to the Secretary, Mr. C. B. Neblette, Rochester Athenæum and Mechanics Institute, Rochester, New York: astronomy, meteorology, light-sensitive substances; photomicrography, microphotography, metallography; X-ray spectrography; cosmic ray photography and theoretical physics; press photography; high-speed photography; technique of colour photography; photography by invisible radiation; aerial photography.

Awards of the Geological Society

THE Geological Society has made the following awards: Wollaston Medal to Prof. Waldemar Lindgren of the Massachusetts Institute of Technology, for his researches concerning the mineral structure of the earth, and especially concerning the problems of mesasomatism, contact ore deposits and the application of physical chemistry to ore deposition; Murchison Medal to Dr. L. J. Spencer, in recognition of the value of his original contributions to mineralogical science and of his services to the publication of mineralogical literature; Lyell Medal to Mr. L. Richardson, for his contributions to the geology of the Jurassic rocks of Great Britain; Bigsby Medal to Prof. C. E. Tilley, in recognition of the value of his researches in petrological science, especially in the petrology of the metamorphic rocks; Wollaston Fund to Dr. D. Parkinson; Murchison Fund to Mr. S. H. Straw; a moiety of the Lyell Fund to Mr. J. F. Jackson; another moiety of the Lyell Fund to Miss M. E. Tomlinson.

Announcements

DR. E. J. BUTLER, secretary of the Agricultural Research Council; Dr. J. B. Conant, president of Harvard University; and Lord Hailey, director of the African Research Survey, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service.

MR. J. RAMSBOTTOM, keeper of botany at the British Museum (Natural History), and a secretary to the Linnean Society of London, who is known for his mycological researches, has been elected an honorary member of the Quekett Microscopical Club.

MR. RICHMOND T. ZOCK, of the U.S. Weather Bureau, has been elected a foreign member of the Royal Meteorological Society.

THE annual general meeting of the Association of Technical Institutions will be held in the Carpenters' Hall, Throgmorton Avenue, London, E.C.2, on February 26–27. On February 26, at 10.45 a.m., the incoming president, the Right Hon. Lord Kennet, will deliver the presidential address. Further information can be obtained from Dr. H. Schofield, Loughborough College, Loughborough, Leicestershire.

THE fourth International Grassland Congress will be held in Great Britain under the presidency of Prof. R. G. Stapledon on July 8–23. The Congress will meet first at Oxford and will then proceed to various places of topical interest including Leicester, Birmingham, Cirencester, Hereford, Aberystwyth, Newcastle and Edinburgh. Further information can be obtained from the Joint Secretaries, Agricultural Buildings, Aberystwyth.

THE Associated Grocery Manufacturers Association of America at the annual banquet on December 1 presented Dr. George R. Minot of Boston with the annual award for research in the field of health leading to the prevention of disease and the advancement of health. The presentation address was made by Dr. Morris Fishbein, editor of the *Journal of the American Medical Association*.

DR. JOHN HOWARD NORTHROP, of the Rockefeller Institute for Medical Research, Princeton, N.J., has been awarded the Charles Frederick Chandler Medal of Columbia University in recognition of his fundamental discoveries concerning bacteria, the constitution of protein and the chemistry of digestion. The medal was founded in 1910 in honour of Prof. Chandler, who taught at Columbia University and was a pioneer in industrial chemistry.

DR. DAVIDE GIORDANO, president of the Italian Society of the History of Medicine and Natural Sciences; Dr. Bernhard Peyer, professor of palæontology at Zurich; and Dr. Brouwer, professor of neuropathology at Amsterdam, have been elected members of the Leopold Caroline German Academy of Natural Philosophy at Halle.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 157.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Exchange of Phosphorus Atoms in Plants and Seeds

IN a letter to NATURE[1] we communicated the results of experiments carried out on maize plants using radioactive phosphorus as an indicator of the behaviour of the phosphorus atoms. The results obtained showed unambiguously that the greater part of the phosphorus atoms present in the leaves and in the roots of the plants investigated is not permanently in one place, but migrates from leaf to leaf. We extended the experiments described above and investigated the behaviour of phosphorus in the sunflower.

The plant was first grown in an ordinary nutritive solution until a set of leaves, which we will call 'lower leaves', appeared. We then placed the plant in a second nutritive solution in which the phosphorus atoms were replaced by 'labelled' phosphorus atoms (mixed with radioactive phosphorus atoms). The second set of leaves, which we will denote as 'upper leaves', were grown in this solution and contained accordingly labelled ('radioactive') phosphorus atoms. For the sake of simplicity we will assume that the 'lower' leaves did not grow further in the second solution but retained their original size; then we must distinguish between two extreme cases: (*a*) the phosphorus atoms do not migrate; (*b*) the phosphorus atoms migrate. In case (*a*) labelled phosphorus atoms should only be found in the upper leaves; in case (*b*) the labelled phosphorus atoms should be equally distributed between the upper and lower leaves.

TABLE 1.

Time in days	Part of the plant	Total P (mgm.)	Labelled P (per cent)	Unlabelled P (mgm.)
0	Lower leaf Upper leaf Stem	0·980	0	0·980
4	Lower leaf	0·848	43·6	0·478
	Upper leaf	0·840	51·5	0·407
	Stem	0·361	63·7	0·131
9	Lower leaf	0·742	66·9	0·246
	Upper leaf	2·838	65·6	0·976
	Stem	0·844	85·6	0·122

As is seen from Table 1, the lower leaves contain an appreciable amount of labelled phosphorus atoms, clearly showing that in the case of the sunflower, just as in that of the maize plant, a very considerable migration of the phosphorus atoms takes place, and the probability of a labelled phosphorus atom being found in a preformed leaf is not very different from the probability of its being found in a leaf grown in a labelled solution. In comparing the figure obtained for the lower and upper leaves, we have to take into account the fact that the lower leaves increase in size to some extent while the plant is in the labelled solution; however, this increase was found to be very slight, as to be seen from the third vertical column of Table 1 and also from Fig. 1, which illustrates the plant at the three different stages of its growth.

From the above, it follows that the greater part of the phosphorus atoms are not fixed in position in the leaves but can migrate. The bulk of the phosphorus atoms found in plants are presumably present as inorganic phosphate, and carried about with the circulation stream in the plant. To what extent the phosphorus atoms present in organic combination are permanently localized is under investigation.

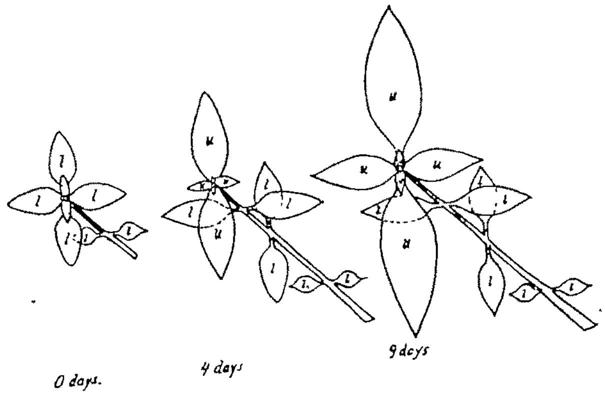

Fig. 1

In connexion with the experiments discussed above, we tried to ascertain if any exchange of phosphorus atoms takes place between an isolated leaf and a nutritive solution. These experiments were carried out with the leaves of a sunflower grown in labelled nutritive solutions. Some of the leaves were ignited and analysed at once after separating them from the stem, while other leaves were placed for 48 hours in a nutritive solution containing unlabelled phosphorus to give a chance for exchange to occur between the labelled phosphorus in the leaf and the normal phosphorus in the solution. No labelled phosphorus could, however, be found in the nutritive solution.

In another set of experiments we placed cut leaves of sunflowers, grown in a normal nutritive solution, in labelled solution for 48 hours; in all the cases investigated an uptake of a few per cent of the labelled phosphorus atoms into the cut leaf was found. As was to be expected, a cut leaf takes up not only the solvent but also the solute from the solution in which it has been immersed.

Finally, we would like to mention some experiments carried out with seeds. Two different series of experiments were carried out, one with maize seeds, the other with those of the pea. In both cases the seeds were germinated until rootlets 2–3 cm. long were formed. Then the seeds were placed in small flasks with the rootlets dipping into a nutritive solution containing labelled phosphorus. In the case of the maize seeds (Table 2) the germ and endosperm were removed after the lapse of 4–14 days and analysed separately. While the germ was found to contain an appreciable amount of labelled phosphorus taken up from the nutritive solution, the endosperm did not contain the slightest trace; this shows that no exchange takes place between the phosphorus atoms of the germ and the endosperm. In the case of the pea, there is no such marked distinction between germ and endosperm, the cotyledons occupying most of the space inside the seed, so that the labelled phosphorus atoms are taken up by the different parts of the seed. The concentration of the labelled phosphorus in the leaves and rootlets was here considerably higher than in the rest of the seed (cotyledons), as is seen from Table 3.

TABLE 2. MAIZE.

No. of days	Part of the plant	Total P (mgm.)	Labelled P (mgm.)
8·9	Rootlet + leaf + scutellum	0·511	0·0134
	Endosperm	0·098	0·0001
7·0	Rootlet + leaf + scutellum	0·778	0·0275
	Endosperm	0·068	0
13·8	Rootlet + leaf + scutellum	1·008	0·0576
	Endosperm	0·016	0

TABLE 3. PEA.

No. of days	Part of the plant	Total P (mgm.)	Labelled P (mgm.)
3·9	Rootlet + leaf	0·167	0·0118
	Cotyledon	0·281	0·0013
7·0	Rootlet + leaf	0·445	0·0411
	Cotyledon	0·314	0·0033
18·8	Rootlet + leaf	0·481	0·0508
	Cotyledon	0·151	0·0050

We wish to express our thanks to Prof. Niels Bohr and Prof. S. P. L. Sørensen for the kind interest taken in this work, and to Miss Hilde Levi for her assistance in the counting experiments.

Organic and Inorganic Chemistry of Iodine Oxides

IN comparing multivalent iodine with multivalent nitrogen, I was led in 1933 to try the action of iodic acid upon aromatic compounds; an unexpected result was found, namely, the copious formation of iodonium salts. The existing knowledge of these proving to be inadequate, a long digression was necessary in which we were able to clear up the main chemistry of iodoxy-compounds and to discover (*inter alia*) that iodine can form compounds in which it recalls 'quinquevalent' arsenic as this is seen in arsinic and arsonic acids; some of the ways in which iodonium salts are derived from iodoxy- and iodoso-compounds were elucidated[1]. Mr. Race and I then reverted to the initial reaction, which takes place in sulphuric acid media of hydration less than $H_2SO_4.H_2O$; from iodic acid and chlorobenzene, for example, one obtains in a single operation an 80 per cent yield of the *para*-iodonium derivative. Benzene similarly yields diphenyl-iodonium salts, and its derivatives with *o*- *p*-directing substituents (provided that these are not too highly activating) react in the same way; while *meta*-directing substituents like the nitro-group prevent the reaction. Particulars of this work will be published.

It appeared, however, that despite the high yields, the action of iodic acid was a secondary one, and that it ensued upon a prior reduction of the iodic acid at the expense of some of the organic reagent. In following this up, I find that if one starts with iodine sesquioxide (in the form of Chrétien's sulphate $I_2O_3.SO_3.\frac{1}{2}H_2O$) instead of iodic acid, in a suitable sulphuric acid medium, the yields of iodonium salts from chlorobenzene become quantitative; and the reaction is very smooth. Further, iodine sesquioxide turns out to be an interesting reagent for effecting, very easily, two new aromatic substitutions. With benzene and its *o*- *p*-directing derivatives, one gets *para*-iodonium salts; with the other type, such as nitrobenzene or benzene sulphonic acid, one gets a direct introduction of the iodoso-group. The orientation of this is *meta*. Thus, for convenience regarding the inorganic reagent as virtually the hydrogen sulphate of trivalent iodine:

(*a*) $RH + HSO_4.I(HSO_4)_2 \rightarrow H_2SO_4 + RI(HSO_4)_2 \rightarrow RIO$;

or, with the less inactive aromatic reagents,

(*b*) $2RH + (HSO_4)_2.I(HSO_4) \rightarrow 2H_2SO_4 + R_2I^{\cdot}.HSO'_4$.

The need to prepare iodine sesquioxide (as its sulphate) has caused me to study anew the inorganic chemistry of the lower oxides of iodine; for the method hitherto used, ultimately derived from Millon, is confused in theory and inconvenient in practice. It consists of heating iodic acid in strong sulphuric acid until iodine boils off along with oxygen, and then awaiting the very slow deposition of a small yield of the desired solid. Some of the main facts disclosed by the present experiments may be presented.

The reaction

$$2I_2 + 3I_2O_5 = 5I_2O_3$$

is a reversible equilibrium; it is displaced towards the left by heat, and wholly (but not instantly) to the left by water, as this converts I_2O_3 into the stable iodate anion; it is displaced to the right by an acid strong enough to convert I_2O_3 into a salt (the cationic nature of trivalent iodine has been plainly indicated by Fichter[2] and others). Thus the sulphate can be got in quantitative yield from iodine and its pentoxide by merely shaking these in cold concentrated sulphuric acid in the proportions stated in the equation. This synthesis goes through an interesting stage; the two reagents, neither of them significantly soluble alone, rapidly dissolve in forming a very deep brown solute which is not iodine but is a compound of a suboxide; the present evidence suggests that it is the sulphate of a radical I_3^+. This then slowly attacks more dissolved pentoxide, the action being slightly reversible but driven towards completion by the insolubility of the product, the pure yellow sulphate of I_2O_3. The dark solute is still being studied, since if the difficulties in the way of its identification can be overcome, it raises interesting points in the electronic behaviour of the iodine atom. It would clearly be related to I_3OH, the brown solute discovered in 1862 by Lenssen and Lowenthal and later examined by Skrabal[3], which is hypoiodous acid co-ordinated with a molecule of iodine.

The thermal dissociations

$$I_2O_5 \rightarrow O_2 + I_2O_3 \rightarrow I_2 + 2\tfrac{1}{2}O_2$$

can be exactly arrested at the middle stage if one heats iodine pentoxide in fuming (instead of concentrated) sulphuric acid, such acid being strong enough to stabilize trivalent cationic iodine as a soluble sulphate even at 220°. It may also be mentioned that fuming sulphuric acid oxidizes elementary iodine, even without heating, forming intense manganate-green or very deep blue solutions, like that of sulphur sesquioxide, and liberating sulphur dioxide.

As to the other intermediate oxides of iodine, IO_2 and I_4O_9, there is good reason to agree with Fichter that they are iodous iodates, and their compositions can be generalized as $I_2O_3 . nI_2O_5$

Bromination of Halogenobenzenes in the Gaseous Phase; Influence of Temperature and Catalysts on the Substitution Type

IN continuation of preliminary experiments[1], we have studied the monobromination of bromobenzene, chlorobenzene and fluorobenzene in the gaseous phase at several temperatures between 380° and 500° C., in the presence of artificial graphite as a contact substance, under well-defined conditions of temperature and rate of gas flow. A few typical results are given in Table 1.

TABLE 1

Temperature	Bromobenzene 380°	440°	480°	530°	Chlorobenzene 375°	475°	Fluorobenzene 360°	500°
Percentage *ortho*	23	26·0	25	18·9	28	20	Not determined	
Percentage *meta*	25	47·2	51	59·0	20	53		
Percentage *para*	52	26·8	24	21·2	52	27	71	24

In these circumstances, the bromination of the halogenobenzenes belongs to the *ortho-para* type (according to the definition of A. F. Holleman[2]) at temperatures below 400°, but to the *meta* type at temperatures above 450°. These results are in disagreement with current theories on benzene substitution.

However, quite different results are obtained when the bromination is carried out with ferric bromide as a catalyst. Within the range 200°–450°, no change of substitution type is observed, but only a gradual change in the relative amounts of isomerides, as is shown in Table 2 for the bromination of bromobenzene:

TABLE 2.

Temperature	Percentage *ortho* Found	Percentage *ortho* Calc.	Percentage *meta* Found	Percentage *meta* Calc.	Percentage *para* Found	Percentage *para* Calc.
200°	16·6	17·3	8·0	7·0	75·4	75·7
250°	20·6	20·1	9·6	8·8	69·8	71·1
300°	23·4	22·4	9·8	10·6	66·8	67·0
350°	23·9	24·4	12·3	12·3	63·8	63·3
400°	25·9	26·2	13·4	13·8	60·7	60·0
450°	27·8	27·6	14·2	15·3	57·8	57·1

The theoretical aspect of the influence of the temperature on substitution reactions in the benzene nucleus has been treated by Scheffer[3]. Using his formula, we were able to calculate the relative proportions of isomerides formed: the agreement between calculated and observed figures is excellent.

It follows from our experiments that in the case of typical *ortho-para* directing substituents like fluorine, chlorine and bromine atoms, the nature of the substituent is not the only determining factor for the substitution type; but that the substitution reaction, in this case a bromination, may belong to the *ortho-para* type or to the *meta* type, depending on the temperature at which the reaction is carried out and on the nature of the catalyst. These new facts should be taken into account in any theory on benzene substitution.

Full experimental details will be published in the *Recueil des travaux chimiques des Pays-Bas*.

Degree of Dissociation of Bi-bivalent Salts in very Dilute Aqueous Solution

THE measurements carried out by Shedlovsky[1] of the equivalent conductivities of solutions of uni-univalent salts in aqueous solution are in good agreement at high dilution with the theoretical equation developed by Onsager[2], but such measurements of conductivities of bi-bivalent salts as are available indicate deviations from theory beyond the magnitude of possible errors of experiment. The equivalent conductivity in this case diminishes far more rapidly with rise of concentration than is predicted by Onsager's equation. Attention has been directed to this point by Davies[3], who calculates dissociation constants for this class of electrolyte. On the other hand, La Mer and collaborators[4] take the view that bi-bivalent electrolytes are completely dissociated in dilute aqueous solution, and support their contention by measurements of activity coefficients of zinc sulphate and cadmium sulphate.

The theory of Onsager has been extended to mixtures of electrolytes by Onsager and Fuoss[5]. According to this treatment of the problem, the mobilities of the cations in a mixed solution, for example, of potassium chloride and hydrochloric acid, are not the same as in solutions containing either of these substances at the same total concentration; and the effect of each cation on the mobility of the other has been calculated. The results have been applied to interpret experimental data for mixed partially dissociated electrolytes in non-aqueous solution by

Mead, Fuoss and Kraus[6]. In a mixed aqueous solution of two completely dissociated electrolytes containing two cations of practically equal mobility and a common anion, this effect should be negligible, and the conductivity of such a mixture should depend only on the mobilities of the ions and on the total concentration. In other words, if the equivalent conductivities of the two electrolytes separately are known over the appropriate range of low concentrations, it should be possible to calculate the conductivity of any mixture of the two, assuming that the conductivities are additive and depend only on the total concentration.

To test this point, I have measured the conductivities at 25° C. of very dilute aqueous solutions over the range 0·00005–0·001 equivalent of calcium and strontium dithionates and the corresponding sulphates, and of their mixtures in which dithionate and sulphate respectively are the common negative ions. The following results appear: (1) The corresponding calcium and strontium salts have almost the same equivalent conductivity throughout the range of concentrations examined. (2) The graph of the equivalent conductivity plotted against the square root of the equivalent concentration deviates sensibly from a straight line only at the highest concentrations examined (3) The slope of this line is in all cases much greater than that predicted by Onsager's equation, using values for equivalent conductivity at infinite dilution obtained by linear extrapolation over a range of a few units. (4) For calcium and strontium dithionates the observed slope is 506, the calculated slope 366 and the equivalent conductivity at infinite dilution 152; the corresponding figures for the two sulphates are 646, 354 and 142 respectively. (5) The salts with the higher equivalent conductivity at infinite dilution give the smaller slope, a result at variance with Onsager's equation. (6) The conductivities of all mixtures examined are additive, usually within the probable limits of experimental error, indicating complete dissociation.

It is intended to extend this work as opportunity offers to the selenates of calcium and strontium and to other bi-bivalent salts. The determination of activity coefficients in dilute mixed solutions, if practicable, should yield results interesting in this connexion.

Surface Temperature of Rubbing Solids and the Formation of the Beilby Layer

RECENT letters[1] have discussed the structure of the Beilby layer, and it may be of interest to describe experiments which throw some light on the mechanism of its formation. Macaulay[2] has suggested that polishing is due to a melting of the surface, but the majority of investigators, Newton[3], Rayleigh[4], Herschel[5], French[6], Adam[7], Hamburger[8], considered that the process is essentially one of abrasion. French embedded a thermometer in the polisher, and concluded that the rise in temperature of the surfaces was negligibly small.

If the sliding contact of two different metals is used as a thermo-couple, the surface temperature can be measured. Experiments show that the local temperatures at the points of contact may be very high; under many conditions of sliding, sufficiently high to cause a real melting of the metal[9]. Even if the surfaces are well lubricated or flooded with water, these local high temperatures still occur. In the case of non-metals of low thermal conductivity such as glass, silk, alumina, etc., the surface temperatures will be very much higher. This localized frictional heating should play a large part in the process of wear, surface flow and polishing of solids. If this view is correct, we should expect the process to be greatly influenced by the *relative melting point* of the polisher and solid. If the polisher melts or softens at a *lower* temperature than the solid, it will melt and flow first, and will have comparatively little effect on the solid. Experiment has shown this to be the case. Surface flow, polish and the formation of the Beilby layer readily occurred on metals, crystals and glasses, provided the melting point of the polisher was higher than that of the solid. The *relative hardness* as normally measured at room temperature was comparatively unimportant.

For example, *camphor* (m.p. 178° C.) readily polished Wood's alloy (m.p. 69° C.) which melts below it, but would not polish higher melting metals such as tin (m.p. 232° C.). *Oxamide* (m.p. 417° C.) polished tin, type metal, etc. and all solids melting below 417° C., but had no effect on speculum metal (m.p. 745° C.). *Lead oxide* (m.p. 888° C.) polished speculum metal, but had no effect on nickel (m.p. 1452° C.) and molybdenum (m.p. 2470° C.). Similar results were obtained for numerous glasses and crystals. Calcite, for example, which melts at 1333° C., was readily polished by *zinc oxide* (m.p. about 1800°) but not by *cuprous oxide* (m.p. 1235° C.) or *oxamide* (m.p. 417° C.). The mechanical strength of many solids falls to a low value at temperatures well below the melting point, so that appreciable surface flow can occur at these lower temperatures. This has been observed in many cases.

The process of polishing is a complicated one, and will be discussed more fully elsewhere. These experiments indicate, however, that an important part of the process is an intense local heating at the points of contact. The melted or softened solid flows, or is smeared, over the surface, and very quickly solidifies to form the characteristic Beilby layer. The extent to which this layer is microcrystalline or 'amorphous' will naturally depend upon the conditions of polishing, rate of cooling, etc., and upon the physical properties of the solid. If oxidizable solids are polished in air, we should expect this local heating to cause rapid surface oxidation. Electron diffraction experiments[10] have shown that the polished layer on copper and aluminium is, in reality, metallic oxide.

Are Viruses Organisms or Autocatalysts?

(1) THE absence of a limiting surface between the material of a virus and its host; (2) the high speed of the transmission of its characteristic symptoms (10–30 cm. per hour) in the tissues of the host; (3) its rapid increase; (4) the vanishingly small quantities needed for inoculation, made me many years ago form the opinion that viruses are more properly regarded as autocatalytic substances than as specific organisms From 1922 on, I have mentioned the idea in my lectures.

This view is now strikingly supported by Stanley's separation from a virus-infected plant of a crystallizable protein, which, when inoculated into a healthy one, produces the symptoms of the virus disease[1]. From the work of Bawden, Pirie, Bernal and Fankuchen[2], it further appears that the molecules of this protein are rod-shaped and are built up of sub-units of the same character.

The facts recently emphasized in Dr. John Caldwell's article[3], namely, that viruses spread most rapidly from growing tissues, where presumably the sub-units of the protoplasmic proteins are in great abundance, and that they travel from cell to cell by way of the plasmodesmata, accord well with the autocatalytic theory. Furthermore, they cannot penetrate through a barrier of dead cells, or through unperforated cell-walls.

No doubt the present workers will test, or have already experimentally tested, the ability of Stanley's protein to catalyse its own production in the extracts from otherwise uninfected cells. It must be remembered that Olitsky has already reported that he has been able to cultivate tobacco mosaic in a simple medium presumably free from cells[4].

Spontaneous Chromosome Changes in Pollen Grains

IN preparations showing the first post-meiotic mitosis in pollen grains of two genera, *Tradescantia* and *Hyacinthus*, I find evidence of spontaneous structural changes in the chromosomes occurring with a high frequency. Some of these changes are of the kind that can be produced artificially by the action of X-rays on the post-meiotic resting stage. They depend on breaks and rejoins between chromosomes or chromatids, according to whether the changes occur before or after the chromosomes have split (Riley[1]. Mather unpub.). These breaks and rejoins lead to the formation of dicentric chromatids and acentric fragments (those having two or no centromeres or spindle attachment chromomeres respectively[2]). At anaphase and telophase the dicentric chromatids form bridges connecting the two daughter nuclei, while the fragments lie passively on the equator.

I have found bridges of this kind in *T. virginiana* ($2n = 18 = 3x$) (Fig. 1*a*). One or more bridges may be present together with a corresponding number of fragments, although these are occasionally not visible. The free arms of the bridges may be equal (Fig. 1*a*) or unequal, showing that at least in some cases non-homologous chromatids have joined up. The difference of size between the chromosomes in this species, however, is slight, so that they are not individually recognizable Cells containing these bridges often occur in groups of two or three, although the aggregate number of changes observed is only of the order of ten or twelve in each flower. The original frequency of change must be greater than this, since the results can be readily detected only at anaphase, and a small proportion of nuclei only are undergoing mitosis at any one time.

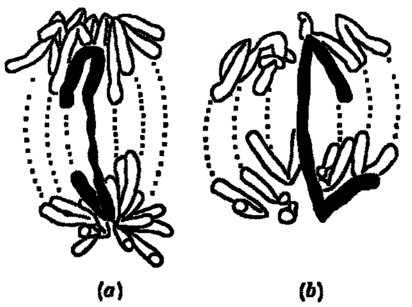

Fig. 1

ANAPHASE OF POLLEN GRAIN DIVISION IN UNTREATED MATERIAL OF (*a*) *Tradescantia virginiana* ($3x = 18$) AND (*b*) *Hyacinthus orientalis* VAR. "WILLIAM MANSFIELD" ($2x = 16$). EACH CELL CONTAINS A DICENTRIC CHROMATID FORMING A BRIDGE. NO FRAGMENT IS VISIBLE. × 1600.

In *Hyacinthus orientalis* variety "William Mansfield" ($2n = 16 = 2x$) (Fig. 1*b*), similar bridges occur with a somewhat lower frequency, but acentric fragments have not usually been seen with them. The bridge is always formed from one of the long chromosomes, and its free arms are always equal. The separation of the remaining chromosomes is normal and there is no evidence of non-disjunction. In such cases, therefore, one of the chromatids of the bridge chromosome must have joined up with its sister, as may also happen with induced changes (Husted[3]). Since fragments are rarely seen, and since the bridge appears to be approximately equal in length to the sum of the free arms (all the long chromosomes have median centromeres), it is presumably the ends that have joined. This conflicts with previous inferences of the inability of chromosome ends to fuse[2].

These structures cannot be the result of crossing-over in inversions at meiosis, since one and not two sister chromatids form the bridge, and further, in the case of the diploid, the normal complement of chromosomes excludes the possibility of non-disjunction. They are therefore the result of spontaneous changes, and changes which differ in both character and frequency from those hitherto inferred.

The Hexlet

DR. FRANK MORLEY has given in NATURE of January 9, p. 72, a very elegant proof of my hexlet theorem which incidentally has enabled me to solve, almost at sight, a further problem on which I had been spending fruitless months. He derives the hexlet with its attendant trio in general from a very simple assemblage, by inversion, namely, from a central sphere surrounded by a ring of six equal spheres between two parallel planes, or spheres of zero bend. The latter invert into two of the spheres of the trio, the central sphere being the third.

To the engineering type of mind at any rate, if not the mathematical, it would be a help to the better understanding of the hexlet if there were some fixed point that could be regarded as the centre and which could be taken as the origin of co-ordinates. I have known for long that the points of serial contact of the infinite necklace of serially touching circles, all in contact with a pair of circles which touch each other, lie on a circle the bend of which is half the difference of the bends of the pair. I therefore expected that the six serial contacts of the hexlet would lie on the surface of a sphere, the centre of which would form the natural fixed point desired.

It is obvious from Dr. Morley's originating assemblage that this is true. The plane midway between the two parallel planes, which contains the six serial contacts and the six contacts of the individual beads of the hexlet with *one* of the trio, also inverts into a sphere the surface of which cuts all the twelve contacts enumerated orthogonally and passes between the other two members of the trio at their point of contact tangentially. Its radius and centre must therefore be those of the 'circle of contacts' of the plane figure, when the assemblage is sectioned through the plane containing the centres of the trio. That is, the centre of this 'sphere of contacts' lies on the line through the centres of the two of the trio between which it passes tangentially, and its bend is half the difference between the bends of these two. I have established this *ab initio*.

The beauty of these propositions, concerning four mutually touching circles and five mutually touching spheres which underlie these assemblages, is that there is absolutely no distinction mathematically between the four circles or five spheres, respectively. It follows that there are, centred in the plane containing the centres of the trio, three different 'spheres of contacts' to each hexlet, intersecting each other, all of which contain the six points of serial contact of the hexlet, and each of which in addition contains the six points of contact of the individual beads of the hexlet with one of the trio, and the point of contact of the other two. This obscured the problem until Dr. Morley's letter furnished the clue. I had actually obtained the correct solution, but since only two of the trio were involved had rejected it as impossible!

Since the line of intersection of spheres is a plane circle, and the six serial contacts of the hexlet lie on the intersection of three spheres, the latter must intersect in the same circle, so that their centres must be in line. I am indebted to Mr. Hodgkinson here for identifying this line for me as one of the axes of similitude of the trio (see Casey's "Sequel to Euclid", 2nd ed., p. 84). It follows that the centres of the six spheres of the hexlet and the six serial contacts lie in a plane. This much simplifies the nature of the assemblage.

The bend, $\varkappa$, of the circle of six serial contacts of the hexlet is given by

$$3\varkappa^2=\alpha^2+\beta^2+\gamma^2-(\alpha\beta+\alpha\gamma+\beta\gamma)$$

or

$$3\varkappa^2=\alpha^2+\beta^2+\gamma^2-\rho^2,$$

where α, β, γ and ρ are the bends of the trio and of the circle inscribed in the triangle joining their centres, respectively. The second form is applicable without ambiguity only when all the bends are positive. By similar reasoning, the contacts of the six beads of the hexlet with each of the trio, respectively, must also lie on a plane circle.

Any hexlet may be fixed and the individual bends of the trio varied, so long as both the sum, and the sum of the squares, of the three bends remain unchanged. So long as the bends of any hexlet associated with a given trio are all positive, one of the bends of the trio may be made zero without changing the hexlet. Thus every such hexlet may be touched by two planes on either side of and equally inclined to the plane of its centres (since it is symmetrical with respect to this plane). This interesting property was discovered experimentally for some of the hexlets of the model illustrated in NATURE (Jan. 9, 1937, p. 78) by Mr. F. March, the mechanic of the Old Chemistry Department, who constructed it. In the limiting case where the bend of one of the beads of the hexlet at its minimum becomes zero, the two planes converge into one normal to the central plane of the hexlet.

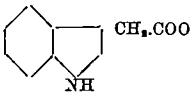
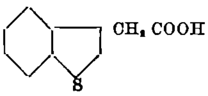
Synthetic Plant Growth Hormones

INDOLE-β-acetic acid or heteroauxine (I) is a product found in normal urine and is well known to have great growth-promoting action on plants, as shown by both the bending of the decapitated oat (*Avena*) and the pea curvature tests.



(I)



(II)

Thionaphthene-β-acetic acid (II) has been synthesized as follows: Thionaphthene → β-bromothionaphthene → thionaphthene-β-carboxylic acid chloride → β-thionaphthene acetic acid, using the reaction of F. Arndt and B. Eisert[1]. The compound melts at 109°, and has a much smaller growth activity than might be expected from its similarity with (I). The oat and pea tests are given by concentrations greater than 1 in 70,000 and 1 in 100,000 respectively, whilst (I) gives a response in dilutions about thirty times greater. It is interesting that an isomeric thionaphthene acetic acid, m.p. 141°, in which the position of the acetic acid group is not yet known, has about the same activity towards peas as (II), but is without effect on oats. A positive response by one method of testing and a lack of response by another method is not unknown; K. V. Thimann[2] shows that coumaryl-*l*-acetic acid gives a positive pea test but no activity in the oat bending test. This and other evidence indicates that the two tests are not necessarily strictly comparable.

Naphthalene-α-acetic acid is several times more powerful than (II), as shown by both oat bending and pea tests. As these two compounds and (I) have many close chemical analogues, it is evident that the biological response is sensitive to very minute changes in the structure, or perhaps diffusibility, of the substances applied.

Carotene Therapy of Retinitis Pigmentosa

THE loss of dark adaptation and night blindness which characterizes the earliest stages of retinitis pigmentosa suggested to us the possibility that one of the fundamental features of the pathological physiology of the disease is failure of utilization of carotene and vitamin A.

Feeding of these substances by mouth in large doses was found to have no effect upon the course of the disease or upon the symptoms in question. We thereupon administered carotene in oil intramuscularly in a series of cases, and were gratified to find a rapid and prompt response and relief of the night blindness. We administered carotene in doses of 30,000–60,000 New U.S.P. units intramuscularly, one to three times a week in our cases. In all the early cases of retinitis pigmentosa, improvement began to be noticeable within one week after institution of therapy; and dark adaptation became comparable to normal, and in some cases, normal within one to four months, with a corresponding improvement in the night blindness. In the more advanced cases with extensive chorio-retinal atrophy, no improvement has yet been noticed.

Our findings indicate that in retinitis pigmentosa there is a failure of assimilation of vitamin A and its precursors. We are planning a study of this phase of the subject. Another finding of interest is that, judging by the response of the cerebral circulation to bilateral carotid pressure—epileptiform convulsions and more or less prolonged loss of consciousness or coma—the arterial circulation of the brain of these cases is as much impaired as is that of the eye.

Diphenyl Compounds and Mammary Growth

DODDS and Lawson[1] have found that it is possible to obtain the œstrus response in castrated animals with substances which do not contain the phenanthrene nucleus. Various dihydroxydiphenyl compounds were tested and found to be active if the two hydroxyl groups were in the *para* position. Certain other compounds, for example, diphenyl-α-naphthyl carbinol, were also found to be active.

Since these substances have œstrogenic properties, it might be expected that they would also function as initiators of mammary growth. Three compounds have been investigated for this effect, *p*-*p*′-dihydroxy diphenyl, 4-4′-dihydroxy-3-3′-dimethyl diphenyl, and diphenyl-α-naphthyl carbinol. The compounds, suspended in sesame oil, were injected subcutaneously into young adult male guinea pigs, 100 mgm. being given once a week for three weeks.

With the diphenyl-α-naphthyl carbinol, nipple growth commenced in a few days, and at the end of the three weeks the nipples had reached a size comparable to that at the end of the first pregnancy in the adult female. Histological examination revealed a limited duct growth, and several fairly extensive lobules of acinar tissue were present. Since the testicles were enlarged, and in some cases protruded through the abdominal wall, it is possible that the compound produced its effect through the endocrine system, and that the mammary response is perhaps due to increased secretion of testosterone. Collip, McEuen, and Selye[2] have found that testosterone can cause the development of acinar tissue in the mammary glands of male animals, though Turner and Gomez[3] state that œstrogenic hormones cannot cause growth of mammary parenchyma in completely hypophysectomized animals, the only effect observed being an extensive growth of the nipple. The answer to the question whether diphenyl-α-naphthyl carbinol acts directly or indirectly in promoting mammary growth must therefore await the results of experiments with castrated and hypophysectomized animals.

In the doses given, the *p*-*p*′-dihydroxy diphenyl caused a slight but definite response, while the 4-4′-dihydroxy-3-3′-dimethyl diphenyl was inactive.

These observations were made during the progress of some experiments designed primarily to investigate the possible effect of the above compounds on lactose synthesis in the mammary gland.

Temperature Variation of the Abnormal Unidirectional Diamagnetism of Graphite Crystals

As is well-known, graphite crystal exhibits some remarkable magnetic properties. The susceptibility along the hexagonal axis of the crystal, $\chi_{\parallel}$, is about -22×10^{-6} per gm., at room temperature, while that along directions in the basal plane, $\chi_{\perp}$, is $-0{\cdot}5 \times 10^{-6}$ only[1]—the latter value being nearly the same as that of diamond. The abnormal diamagnetism of graphite is thus more or less confined to one direction. Further, this abnormal diamagnetism is very sensitive to any chemical treatment of the crystal. For example, on treating the crystal with a mixture of strong nitric and sulphuric acids, when it swells up to 'blue graphite', $\chi_{\parallel}$ diminishes numerically from -22×10^{-6} to less than -2×10^{-6}, whereas $\chi_{\perp}$ remains practically unchanged. Also an indefinite diminution in the size of the crystal appears to have the same effect.

We have recently studied the temperature variation of the principal susceptibilities of graphite, and the results may be of some interest in connexion with recent discussions on the contribution of 'free' electrons to diamagnetic susceptibility and its dependence on temperature[2]. The results are represented graphically in Fig. 1. As will be seen from the curves, the magnetic anisotropy of the crystal, namely, $\chi_{\parallel} - \chi_{\perp}$, which was measured directly, diminishes numerically from about -28×10^{-6} at 140° K., to about $-7 \cdot 8 \times 10^{-6}$ at 1,270° K., whereas the corresponding variation of $\chi_{\perp}$ is from about $-1 \cdot 4 \times 10^{-6}$ at 100° K., to $-0 \cdot 5 \times 10^{-6}$ at room temperature, and to $-0 \cdot 4 \times 10^{-6}$ at 940° K.

Examination of Passive Iron by Electron Diffraction

BY Dr. U. R. Evans's method[1] of electrolysis, almost transparent thin films were detached from the surface of electrolytic iron made passive by immersion in potassium chromate solution. These films were examined by means of a cathode ray of about 50 kilovolts. Spacings of the diffracting substance were calculated from the diameters of several diffraction rings and it was found, as the accompanying table shows, that the films are composed of γ-Fe_2O_3 or Fe_3O_4.

Rings	Indices of planes	Spacings (A.)	Side of unit cube (A.)
1	(200)	4·22	8·44
2	(220)	2·95	8·34
3	(311)	2 51	8·32
4	(400)	2 07	8·29
5	(422)	1·68	8·24
6	(440)	1·48	8·38
7	(600)	1·39	8·34

mean a_0 = 8·34 A.
a_0 for Fe_3O_4 (X-ray) = 8·37 A
a_0 for γ-Fe_2O_3 (X-ray) = 8 4 A.; 8·30 A.

As γ-Fe_2O_3 and Fe_3O_4 have almost the same spacings, it is impossible to distinguish between the two oxides. From chemical tests, however, we believe this oxide to be γ-Fe_2O_3. The films are ferro-magnetic and it is certain that they are not α-Fe_2O_3, contradicting the views of many previous workers. Good films are difficult to detach from the surface of iron (not passive) polished in air; but a few samples, fortunately obtained after considerable efforts, proved to be also γ-Fe_2O_3. The conclusion is that passive iron is a state of iron the surface of which is covered in a perfectly compact manner by a thin film of γ-Fe_2O_3. No clear diffraction pattern was obtainable by the reflection method, but three spacings (4·22 A., 2·51 A. and 1·48 A.) were calculated from the vague rings. No rings were observed by the reflection method from iron made passive in concentrated nitric acid, and no film was detached from it.

Details will be reported in the Scientific Papers of this Institute.

Geodesics within Matter

THE difficulties regarding the physical interpretation of null-geodesics and time-like geodesics inside matter, discussed in a recent letter by Dr. Silberstein[1], may be met by recourse to a process analogous to that employed in the classical theory of attractions. Thus, to measure intensity of force at a point in a medium, we carve out a small cavity and measure the force (or acceleration of a free particle) in the cavity.

There does not appear to be any difficulty in accepting Einstein's postulates that null-geodesics give the histories of light-pulses and time-like geodesics the histories of free particles, provided that in the application of these principles inside a continuous medium we understand that a thin tunnel in space-time is hollowed out to allow the light-pulse or particle to travel freely *in vacuo*. On that understanding, the Newtonian acceleration inside a small cavity in a liquid sphere agrees with the Einstein acceleration, as expressed in Dr. Silberstein's letter.

Feeding Habits of Stick Insects

IN reference to the communication from Mr. Sidney T. E. Dark[1], and the observations from the Notre Dame Training College, Glasgow[2], relating to the eating of dead cellulose by *Carausius*, it may be of interest to record that these insects will occasionally eat paper.

When, some years ago, living stick insects were placed on exhibition in this Museum, temporary labels were suspended inside the cages. The labels were of two kinds, some of common white card resembling Bristol board, but not so tough, and others of thin strawboard faced with white paper. Some of the adult insects used to feed on the edges of these labels—arranging themselves astride the labels in the same attitude as when they fed on the fresh privet leaves with which they were provided. In the course of two or three days, the labels—particularly those of strawboard—were so mutilated and diminished in size as to be useless, and they had to be removed and replaced by others protected by glass The insects were not observed to eat their sloughs; the nibbling of the antennæ of individuals in an akinetic condition seems to be a common habit of those in captivity.

Adjustable Resonators and Orchestration

THE major difficulty in adopting Prof. Osborne's idea[1] of adjustable resonators in orchestral instruments is that it is not easy to make a change of pitch in an instrument without a change of quality. The same is true, to a less extent, of the voice. The wood-wind have resonators the length of which is adjusted to vary the pitch, but there is a consequent difference in timbre between the upper and lower notes of their registers, notably in the clarinet. To preserve the same quality while the pitch varies would involve a complicated system of levers to alter the bore of the—presumably flexible—tube, which would render the execution of rapid passages impossible. On keyboard instruments, with one or more vibrators to each note, another difficulty would arise. Adjustments of the resonator would react on the vibrator, whether string, reed or edge tone, to such an extent as to cause considerable changes of the intensity, or even complete stoppage of the sound

Sounds received by membranes loaded on one side—to imitate the ear-drum and associated ossicles—have been analysed by Waetzmann[2]. His object was to find how much distortion was introduced by this asymmetric loading of the receiver, and he was thus able to explain the formation of 'subjective' combination tones in the ear.

Points from Foregoing Letters

BY growing sunflower plants which have already developed their lower leaves in nutritive solutions containing radioactive phosphorus, Prof G. Hevesy, K. Linderstrom-Lang and C. Olsen find that, as in the case of the maize plant, a considerable migration of phosphorus atoms takes place from the lower to the upper leaves during the subsequent growth The bulk of the phosphorus is present as inorganic phosphate, and probably moves about in the plant, but none of it escapes when cut leaves are placed in a nutritive solution. Germinating maize and pea seeds take up the labelled (radioactive) phosphorus in the germ but not in the endosperm, showing that there is no phosphorus exchange between the two.

Prof. Irvine Masson reports a number of new interrelated facts in the organic and inorganic chemistry of iodine, including the one-stage formation of aromatic iodonium salts, the direct replacement of aromatic hydrogen by the iodoso-group by a new substituting reagent, and the principles controlling the reactions between iodine, its pentoxide and its sesquioxide and a coloured suboxide, especially in sulphuric acid media.

Tables showing the influence of temperature and catalysts upon the position (*ortho-*, *meta-*, *para-*) taken by bromine and other halogen atoms when they are substituted in the benzene molecule are given by Prof. J. P. Wibaut and M. van Loon.

Some measurements of the conductivity of mixed solutions of bi-bivalent salts are described by E. A. O'Connor These are considered to favour the complete dissociation theory, although the measurements are not in agreement with the results to be expected from Onsager's equation

Dr. F. P. Bowden and T. P. Hughes give examples showing that polishing takes place when the melting point of the polishing material is higher than that of the solid to be polished. The relative hardness, as normally measured at room temperature, is comparatively unimportant. This agrees with the observations that the high temperatures developed during friction are sufficient to cause surface flow. Such high temperatures have been observed at the sliding contact of two different metals acting as a thermocouple

Using as criteria of 'organisms' the presence of a limiting surface, low speed of transmission, slow rate of increase, and lack of crystallinity, Prof. H. H. Dixon classifies viruses as autocatalysts and not as organisms.

Structural changes in the chromosomes of the pollen grains of the hyacinth and of *Tradescantia* are described by Miss M. Upcott These changes are apparently due to breaks and rejoins between the chromosomes and lead to the formation of bridges connecting the two daughter nuclei during certain phases of the division process (anaphase and metaphase).

Several new properties of the "hexlet" and propositions concerning four mutually touching circles and five mutually touching spheres are described by Prof. F. Soddy.

The growth-promoting effects upon oat and pea seedlings of certain synthetic organic compounds (thionaphthene-β-acetic acid, coumaryl-*l*-acetic acid) are briefly described by E. M. Crook, Dr. W. Davies and Miss N. E. Smith. There are indications that the pea and oat tests of these compounds are not strictly comparable.

Favourable results in the treatment of night-blindness by intramuscular injection of carotene or vitamin A are reported by Drs. E M. Josephson and M. Freibergor.

According to Prof. J. L. Synge, if thin tunnels of matter are removed from a continuous medium to permit the free passage of a light-pulse or particle, the difficulties recently raised by Dr. L. Silberstein, regarding the physical interpretation of Einstein's geodesic principles inside matter, disappear.

Research Items

Prehistoric Motives in Modern Chinese Art

MR. CARL SCHUSTER, who is at present engaged in collecting examples of folk design in western China, chiefly in the form of cross-stitch embroidery, points out in *Man* of December that these designs often show a marked divergence from the rest of Chinese art, and are evidence of early foreign influence. The design here under consideration in particular is a wavy line similar to the M or W marks which occur frequently in archaic Greek pottery and in predynastic Egyptian art, where they have been interpreted by Herbert Kuhn as signs for water and, by extension, for fertility. This interpretation has also been applied to the zig-zag which appears in European prehistoric pottery from neolithic to iron age times. The suggestion is supported by their occurrence on vessels which would have been used for storing liquid A favourite motive in western Chinese embroidery design is a vessel, out of which grows a plant, the Tree of Life. On these pots the zigzag decoration is persistent, but it rarely appears in any other examples of this class of work. The zigzag as a mark on vessels is not confined to embroidery. It also appears on vessels in stone carving, as, for example, on a wayside shrine. It also appears in blue tape on the seat covers of the rickshaws of the city of Ch'ungking in Szech'uan, where it forms an essential part of the design, though this has been much simplified. In the embroidery designs, folk art has sometimes borrowed from the professional. It shows the 'professional' scale pattern on the bottom of the vessel, while the popular zigzag appears on the neck, thus expressing the same idea in two 'languages'. As these embroideries are some eighty years old and are not made by the present generation, no trustworthy account of their meaning can be obtained. Of the alternative origins, independent invention and an unbroken cultural transmission, the latter is thought to be the more probable.

Tumours Transplantable with Viruses

DR. W. E. GYE and Dr F. Pentimalli each discuss the problem of the transmission of tumours from one animal to another by means of viruses, in papers read at the cancer congress in Brussels last autumn ("Reports of the Second International Congress of Scientific and Social Campaign against Cancer", Brussels, 1936). It is twenty-five years since Peyton Rous discovered fowl tumours which could be transmitted to other fowls with cell-free filtrates The agent concerned in the transmission of these tumours is particulate and approximately 0·1 micron in diameter. With the growth of the tumour, these particles multiply, but the fact that they never increase outside the cells of the host and that their behaviour in immunological reactions is like that of proteins suggests that they are non-living agents. Peyton Rous has recently experimented with a papilloma of a cotton tail rabbit which can be filtered like other viruses, and this virus injected into an animal bearing a non-malignant papilloma produced by painting with coal tar causes such a papilloma to become rapidly malignant. Dr. Gye suggests that the carcinogenic tar prepares the tissue so that it gives a malignant reaction to a virus When the virus of a fowl tumour is injected into mammals, the mammalian serum acquires the power of neutralizing the virus of the tumour, and this anti-tumour serum will inactivate extracts of the original tumour and of other fowl tumours even without complement. If extracts of normal fowl tissue are injected, the mammalian serum will only neutralize the fowl tumour virus in the presence of complement and differs from the anti-tumour serum in that the tumour neutralizing power is absorbed by normal fowl cells. The tumour virus thus seems to have two parts, one probably typical of the fowl and another more specific part possibly derived from nuclear material from the malignant tissue.

Japanese Cœlenterates

IN 1935 (*Mem. College of Science, Kyôtô Imperial University*, Series B, 10), Dr. Taku Komai described *Stephanoscyphus*, the scyphostome stage of the primitive peromedusa *Nauritho*ё from shallow waters around Seto. He now finds a second form ("On Another Form of *Stephanoscyphus*, found in the Waters of Japan", *ibid.*, 11, No. 3; 1936) of this peculiar cœlenterate, which is probably specifically distinct. This is provided with conical projections on the inner wall at regular intervals, exactly as in the forms previously described by Allman and Schulze from the Mediterranean, and these projections are absent in the specimens from Seto. On this feature and other differences, the author classifies the genus *Stephanoscyphus*, distinguishing four different kinds. In a second paper ("The Nervous System of Some Coelenterate Types. (1) *Coeloplana*") the same author uses the vital staining method with rongulit white. He finds that in *Cœloplana bocki* the dorsal side contains no nerves except in the marginal zone where nerve cells, probably sensory, are found in abundance. The ventral side shows nervous elements all over, but especially in the marginal region. In the polar plates "nerve-cell-like" bodies occur in the region between the central and marginal areas. Otherwise there is no element resembling nerves in the sense-organ or in the parts surrounding it.

The Sub-Genus *Protoperidinium*

IN a recent paper (Report of the Biological Survey of Mutsu Bay, 30. Notes on the Protozoan Fauna of Mutsu Bay. III, Sub-genus *Protoperidinium*: Genus *Peridinium*. *Sci. Rep. Tôhoku Imp. Univ.*, Fourth Series (Biology), Sendai, Japan, 11, No. 1. July 1936), Tohru Hidemiti Abé re-adopts the sub-genus *Protoperidinium* Gran and Paulson in a somewhat modified form, whilst Dr Bohm (Bull. 137, Bernice P. Bishop Museum) does not use it at all. Dr. Abé's paper only includes 7 species, 4 of which are new, and none of these is mentioned in Bohm's paper. The subdivision of the genus *Peridinium* is always controversial, and the fact that Dr Abé has found a close relation between the general features of the ventral area and its plate patterns on one hand, and the type of the hypotheca other than the ventral area on the other hand, together with some diversities in the type of ventral area and constancy in the structural relations of this area, seems to be a distinct advance in our knowledge of the structure of these forms. Six groups are recognized in the sub-genus, three of which are here considered, the other three being left for a later paper. The details of the ventral area in the species described are beautifully figured, and the paper is an important contribution to the morphology of the genus.

Germinal Layers and the Larva in Amphibia

IF a slit be made in the neurula of an Amphibian egg, it is possible by means of glass needles and a hair loop to remove the internal germinal layers, that is entoderm and mesoderm, entirely, or such parts of them as may be selected. O. Mangold (*Naturwiss.*, Nov. 27, 1936) has employed this method to analyse the extent of the co-operation between the germinal layers in the formation of the larva. The removal of the entire entoderm may result in a fairly normal embryo in appearance but lacking gill slits, gill bars, alimentary canal except for the ectodermal proctodœum, most of the blood corpuscles; also the heart is only poorly developed. On cutting the embryo transversely and removing the entoderm from the two halves, the front half develops into a more or less distorted head end often associated with the approximation of the eyes or the establishment of a cyclopic condition. The tail half produces an almost normal tail end including a proctodœum. If the entoderm is extracted whole, the anterior fifth swells to form a vesicle representing the fore gut, but the hinder four fifths remain in a clump not forming liver, pancreas, stomach, etc. Further experiments include the insertion of the entoderm of *Triton tæniatus* into the ecto- and mesoderm of *T. alpestric* in a normal, inverted, or reversed position.

Cordyceps and *Isaria* Fungi

Cordyceps militaris is one of the spectacular fungi; it forms perithecia upon lepidopterous larvæ. *Isaria farinosa* is also an entomogenous fungus which occurs upon a wide variety of insects, from which it produces small white, floury conidiophores. The mycologist Tulasne considered *I. farinosa* to be the conidial stage of *C. militaris*, and though considerable doubt prevailed, his conclusions were generally accepted. Mr. T. Petch has recently elucidated the problem (*Trans. Brit. Mycol. Soc.*, 20, Parts 3 and 4, Nov. 1936). He has shown that the two fungi are quite distinct. The conidial stage of *C. militaris* is not *Isaria*, but a species of *Cephalosporium*. The perithecial stage of *I. farinosa* is unknown; it has no connexion with *Cordyceps*.

Lilacs

THE term lilac is usually interpreted to mean the European shrub *Syringa vulgaris*. Flowers of this plant are indeed beautiful, but a paper by Mr. H. G. Hillier (*J. Roy. Hort. Soc.*, 61, Part 11; 1936) shows that most of the other twenty-seven species of the genus *Syringa* are no less worthy of attention by gardeners. Lilac species are, with the exceptions of *S. vulgaris* and *S. Josikaea*, Asiatic plants, and their advent to horticulture is due to the activities of plant collectors in comparatively recent times. *S. japonica*, *S. pekinensis*, *S. reflexa* and *S. pinnatifolia* are specially commended for attention by virtue of the photographs which embellish the paper, but full descriptions of many other species also appear. Practical considerations of propagation and culture, and a comprehensive description of varieties of the common lilac, are also included.

Non-Disjunction and Trisomics in *Oenothera*

AN analysis of the disjunction arrangements in an *Oenothera* having a ring of fourteen chromosomes has been made by Mr. C. E. Ford (*J. Genetics*, 33, No. 2), who found a non-disjunctional arrangement in 46 per cent of the pollen mother cells. In *O. biennis*, with rings of 6 and 8, he found only 17 per cent. In the ring of fourteen, three cytologically distinguishable types of non-disjunction were recognized: (1) double non-disjunction on opposite sides, (2) on the same side, (3) three-in-a-row non-disjunction. Three varieties of type (1) will occur, but all will produce non-viable gametes. Type (3) leads to the formation of type *A* gametes, having all the chromosomes of one complex plus one from the other complex, and certain classes of them will be viable. In type (2) the disjoining chromosomes may be separated by 1 and 9, 3 and 7 or 5 and 5 chromosomes in the ring, thus forming the *B*, *C* and *D* types of 8-chromosome gametes. There will be 14, 14 and 7 different gametes of these types respectively, thus making a total of 49 possibly viable different 8-chromosome gametes. As non-disjunction occurs in the megaspores while non-disjunctional pollen grains are not functional, and each of the 49 different 8-chromosome megaspores can combine with either complex of the pollen, 98 possibly viable primary trisomic mutants can result. The possible trisomics in species with chromosome rings of different sizes are also determined, as well as the catenations in various interchange trisomics. It is found that the latter should occur in *O. Lamarckiana* about once in 100,000 plants.

Solar Radiation at Calcutta

PROF. P. N. GHOSH, Dr. A. C. Ukil and Mr. M. K. Sen (*J. Ind. Med. Assoc.*, November 1936), in a paper on the extent and intensity of extreme ultra-violet solar radiation at Calcutta, review the literature and describe a photographic photometric method which they devised not only to determine the intensity of the extreme ultra-violet biologically active solar rays but also to ascertain their daily and monthly modifications at Calcutta. The method consists of two operations. The first consists in taking spectrograms of the desired radiation along with that of a standard source, while the second is a measurement of the degree of blackening produced in the different spectral regions by the two sources as well as the estimation of the characteristics of the plate in these regions. The authors' investigations, which are illustrated by tables and charts, show that the ultra-violet intensity of the biologically active region of sunlight at Calcutta is highest during June, though the maximum extension was found in July. It decreased rapidly, however, in May as well as in July. The curves for March, April and May indicated a very weak ultra-violet intensity, while during the period May to September the afternoon intensities were much more pronounced than those of the morning. In the winter months, the reduction in intensity was very marked during the mornings. In conclusion, the authors emphasize the importance of the estimation of intensity of biologically active rays in the selection of sites for sanatoria in different parts of India and especially in the different hill stations.

Excitation of Phosphors in a Neon Discharge Tube

INTERESTING work on the excitation of zinc sulphide and zinc silicate phosphors by ultra-violet and Schumann radiation is reported by A. Ruttenauer (*Phys. Z.*, **37**, 810; 1936). The phosphors were placed in the neon discharge, the exciting radiation being the ultra-violet region of the discharge (4000–2500 A.), and the resonance lines of wave-length 736 and 744 A. By a special arrangement of tubes, it was possible to separate the phosphorescence due to excitation by these two regions. The zinc sulphide phosphors were excited in both regions, but the phosphorescence in the Schumann rays was less intense the higher the current density. Commercial samples of zinc silicate were not excited at all; but it was found possible to prepare specimens which were strongly excited in the Schumann region, but not in the ultra-violet. The phosphorescence radiation converts the usual red colour of the neon discharge into yellow. It seems possible that discharge tubes containing phosphors may find commercial application.

The Micro-Gap Switch

IN a paper read to the Institution of Electrical Engineers on December 17, Prof. W. M. Thornton described the micro-gap switch, which should prove useful in the thermostatic control of the temperature of electrically heated water. The alternating current circuits to be broken are those of the heaters controlling the hot-water or air supply for buildings. To do this, the switch is operated by a bimetallic device which, in the hot-water thermostat, consists of a non-expanding rod contained within an expanding sleeve. The length of the gap is adjusted so that the A.C. current, after passing through its zero value, cannot restrike. On a 250-volt circuit, the opening of the gap is about 0·005 inch. When the contacts separate, the current can have any value from zero to the maximum. Oscillographic records show that at whatever point in the cycle the contacts open, the current stops at the next zero point and does not restrike. If a break greater than the free sparking distance were formed instantly in a non-inductive circuit, there would be no arc, for the contacts would not have time to get hot, no electrons would be emitted, and the arc or break-spark could not form. To keep the contacts cool at break, many devices have been invented. In general these are for large power circuits. For relatively small powers and circuits which are practically non-inductive, the micro-gap switch is available and it is stated to act perfectly.

Physico-Chemical Factors in Cancer

WORKING in Buenos Aires, Dr. A. H. Roffo has obtained tumours in more than seventy per cent of animals exposed to the sun or to the light from mercury vapour lamps. The tumours developed on those parts which are not protected from radiation, such as the ears, eyes, nose and forelegs, but also on other parts of the body if hair were artificially removed. The radiation produced an increase in cholesterol content of the skin, and cholesterol in the presence of ultra-violet light becomes photo-active, possibly by being changed to a hydrocarbon and emitting photo-electrons. The production of cancer by solar radiation may therefore be due to a physical radiation or to a chemical carcinogenic agent produced by the photochemical action of such radiation. The results of this work are discussed in a paper in the "Reports of the Second International Congress of the Campaign against Cancer" (Brussels 1936). The photoluminescence and fluorescence of cholesterol and the relation of other physical conditions to cancer is discussed in the same volume by Vles and de Coulon.

Mandelic Acid in Urinary Infections

THE treatment of the troublesome *Bacillus coli* infections of the urinary tract has advanced during the last two years by the introduction of mandelic acid. Several preparations of this acid can now be obtained for treatment (see NATURE, **138**, 649; 1936), one of the latest introductions being the "Collosol Brand Phospho-Mandelate" of the Crookes Laboratories, Park Royal, London, N.W.10. An essential condition for successful treatment with this drug is an acid condition of the urine, which at first was obtained by the simultaneous administration of ammonium chloride, the taste of which is, however, objectionable, and this is replaced in the Crookes Laboratories preparation by ammonium phosphate, which is not unpleasant as well as being more efficient for the purpose than ammonium chloride. On the first day of treatment, four doses of ammonium phosphate only (contained in a blue envelope in the package) dissolved in water are given to establish a proper acidity, and on subsequent days four doses of ammonium phosphate and of mandelic acid (contained in a white envelope) are similarly given in water. Test-papers are also supplied, by means of which the proper acidity of the urine may be determined. Six days' treatment will frequently clear up an obstinate and long-standing infection, provided this is caused by the *Bacillus coli*.

Photo-electric Photometry of Stars

MENTION was made in NATURE (**133**, 801; 1934) of a new photo-electric photometer constructed by J. S. Hall for obtaining infra-red magnitudes of stars. Dr. Hall has recently used another photometer of similar type in conjunction with the 24-in. refractor at Swarthmore College (*Astrophys. J.*, **84**, 369). Infra-red magnitudes of 281 *K*-type stars were obtained from comparisons of the effective stellar energy at 8300 A. with that of a controlled incandescent lamp, the zero point being determined from similar observations of *A*0 stars. These infra-red magnitudes were compared with Hertzsprung's photographic magnitudes to form one measure of the colour magnitude for each star, which was then combined with published values of colour from Sproul and Berlin-Babelsberg to give a mean value of colour. A mean of three accurate spectral classifications (Harvard, Mount Wilson and Victoria) was used as the adopted spectral type for determining the colour excess. A discussion of the results shows that the correlation between colour excess and absolute magnitude suggested in the previous paper is confirmed for giant stars of types *K*1-*M*0 and possibly for the *G*4-*K*0 types, though it is much weaker for the latter stars. As a method of determining absolute magnitudes of giant *K*-type stars it is simpler than the spectroscopic method, though probably not so accurate.

Prize Awards for 1936 of the Paris Academy of Sciences

AT the annual public meeting of the Academy of Sciences held on December 21, 1936, the prizes and awards for the year 1936 were announced as follows:

Mathematics.—The Poncelet Prize to Paul Lévy, for the whole of his mathematical works; the Francœur Prize to Claude Chevalley, for his work on the theory of bodies of classes.

Mechanics.—The Montyon Prize to Louis Bergeron, for his work on hydraulic machines; the Fourneyron Prize to André Tenot, for his work on hydraulic turbines; the Boileau Prize to Max Teissié-Solier, for his hydraulic researches on the natural turbulent regime; the Henri de Parville Prize to Henri Poncin, for his work in hydrodynamics.

Astronomy.—The Lalande Prize to Louis Boyer, for his work on the minor planets; the Benjamin Valz Prize to André Couder, for his work on optical instruments; the Janssen Medal to Henry Norris Russell, for his important work on stellar astronomy.

Geography.—The Delalande Prize to Jean Rothé, for his observations and researches on the physics of the globe and physical geography carried out in Greenland (Scoresby Sound); the Gay Prize to the Institut scientifique chérifien, for work on the natural resources of Morocco; the Binoux Prize to Edouard de Martonne, for the whole of his work on colonial cartography.

Navigation.—The Prix de la Marine to René Perrin, for his studies on the working of self-propelled torpedoes; the Plumey Prize to René Norguet, for his studies on marine boilers.

Physics.—The L. La Caze Prize to Jean Becquerel, for the whole of his work in magneto-optics; the François Hébert Prize to Georges Albert Boutry, for his researches on photo-electric cells and their applications; the Hughes Prize to Marcel Laporte, for his researches on the electric discharge in gases; the Paul Marguerite de la Charlonie Prize to Henri Abraham, for the whole of his scientific work; the Clément Félix Foundation to Mlle. Nine Choucroun, for the continuation of her work on electrophoresis.

Chemistry.—The Montyon Prize (Unhealthy Trades) to Paul de Graeve, for his work on phosgene; an honourable mention (1,500 francs) to Jean Le Bras, for his contribution to the study of the extinguishing powers of various materials on flames; the Jecker Prize to Charles Dufraisse, for his work in organic chemistry; the L. La Caze Prize to Paul Job, for his work on inorganic complex compounds and on the application of physical methods to chemistry; the Cahours Foundation to Arthur Brunel, for his researches on fungi; the Houzeau Prize to Maurice Rangier, for his work on uric acid and its complex compounds; the Charles Adam Girard Prize to Georges Kravtzoff, for his work on the electrolysis of organic salts of copper.

Mineralogy and Geology.—The Cuvier Prize to Emile Félix Gautier, for his work on the physical geography of Madagascar and the Sahara; the Victor Raulin Prize to Henri Longchambon, for his researches on clays.

Botany.—The Desmazières Prize to Camille Sauvageau, for his work entitled "Sur quelques algues phéosporées de Guéthary"; the Montagne Prize between Germain Chalaud, for his work "Groupe de Cryptogames: les Hepatiques", and Jean Chaze, for his work on the culture of the Saprolegniæ and the diseases of cultivated mushrooms; the De Coincy Prize to Désiré Bois, for the whole of his work.

Rural Economy.—The Demolombe Prize to Félicien Bœuf, for his work entitled "Les bases scientifiques de l'amélioration des plants".

Anatomy and Zoology.—The Da Gama Machado Prize to Pierre Cappe de Baillon, for his work on phasmid insects; the Savigny Foundation to René Dieuzeide, for his work on the Algerian coastal fauna and their parasites; the Jean Thore Prize to Gaston Portevin, for his book on the natural history of French Coleoptera.

Medicine and Surgery.—The Montyon Prize between Léon Delhoume (2,500 francs), for his book entitled "Dupuytren", Marius Piéry (2,500 francs), for his book on biological and medical climatology, and Pierre Rigaud (2,500 francs), for his book entitled "Le labyrinthe, étude physio-pathologique et clinique"; honourable mentions (1,500 francs) to Jacques Courtois and Raoul Lecoq, for their work on puerperal infections, and to André Feil, for his book entitled "Le travail de l'ardoise et la pathologie professionalle de l'ardoisier"; a mention (1,500 francs) to Maurice Sourdille, for his book "Traitement chirurgical de l'otospongiose"; citations to Emile Gilbrin and to Georges Fabiani; the Barbier Prize to Bernard Gouzon, for his book "Sur l'etude de quelques Porphyrines naturelles. Application aux pigments fluorescents de l'œuf des oiseaux"; the Bréant Prize to Jean Laigret, for his work on yellow fever and preparation of the vaccine; the Godard Prize to Pierre Foyel, for his book "Le tube urinaire dans le série animale"; the Mège Prize to Joseph Magrou, for his memoir on the scientific work of Maurice Nicolle; the Bellion Prize to Marcel Belin, for his book "Coquillages et fièvres typhoides"; the Baron Larrey Prize to Pierre Oudard, for his memoir on the organization and working of the health service of the navy at sea in time of war; the Charles Bouchard Prize to Mario Lebel, for his work on traumatisms of the liver; the Jean Dagnan-Bouveret Prize to Claudius Regaud, for the whole of his researches in histophysiology and in normal and pathological radiophysiology.

Cancer and Tuberculosis.—The Roy-Vaucouloux Foundation to Léon Volluz, for his work on experimental production of cancer with polycyclic hydrocarbons; the Louise Darracq Prize to Charles Oberling and Maurice Guérin, for their work on the production of tumours by means of transmissible leucæmia of fowls; the Eugène and Amélie Dupuis Prize to Ernest Coulaud, for the whole of his work on tuberculosis.

Physiology.—The Montyon Prize to Georges Vanhems, for his work on the biochemistry of potassium; the L. La Caze Prize to Charles Dhéré, for his physiological work especially on the spectrography of biological materials; the Pourat Prize to Roger Gautheret, for his memoir on the culture of plants, and attempts at the culture of meristematic tissues; the Martin-Damourette Prize to Daniel Bovet, for his pharmacological researches especially on the derivatives of aminomethylbenzodioxan.

Statistics.—The Montyon Prize to Michel Huber, for the whole of his work in statistics.

History and Philosophy of Science.—The Binoux Prize between Paul Nève de Mévergnies (2,000 francs), for his memoir on Jean Baptiste van Helmont, and Charles Cabanes (1,500 francs), for his work on Denys Papin.

Works of Science.—The Henri de Parville Prize between Georges Bruhat (3,000 francs), for his book on thermodynamics, electricity, optics and physical mechanics, Guillaume Grandidier (2,000 francs), for his atlas of the French colonies, protectorates and territories under French mandate, and Pierre Gauja (2,000 francs), for his study on "L'Académie des Sciences de l'Institut de France".

Medals.—The Berthelot Medal to Paul de Graeve, Paul Job and Maurice Rangier.

General Prizes.—Prize founded by the State (mathematical sciences) to Maurice Gevrey, for his work on partial differential equations; the Bordin Prize to Henri Termier, for his important geological studies on central Morocco and the northern Moyen-Atlas; the Lallemand Prize to Ivan Bertrand, for his memoir on micrography in infra-red light and its application to renal cytology; the Vaillant Prize to Père Lejay, for his researches on the determination of gravity in the Far East; the Le Conte Prize to the late Julien Costantin, for the whole of his work; the Jean Reynaud Prize to Alfred Lacroix, for the whole of his scientific work; the Baron de Joest Prize to Paul Robert, for his researches on anallagmatic geometry and its relations with projective geometry; the Houllevigue Prize to Etienne Wolff, for his researches in experimental embryogeny and teratogenesis; the Parkin Prize (2,400 francs) to Jean Jacques Bouckaert and Fernand Jourdan, for their work on the pharmacodynamics of the cerebral vessels; an encouragement (1,000 francs) to Bernard Ménétrel, for his memoir on intravenous activated carbon in therapeutics; the Saintour prize to Robert Weill, for his work entitled "Contribution à l'étude des Cnidaires et de leur nématocystes"; the Lonchampt Prize to Paul Meunier, for his researches on aluminium in animals; the Henri Wilde Prize to Georges Dupont, for the whole of his chemical work; the Caméré Prize to Lucien Chadenson, for his work in hydraulics; the Gustave Roux Prize to Henri Erhart, for his treatise on pedology; the Thorlet Prize to Paul Dorveaux; the Albert I of Monaco Prize to Fernand Holweck, for his work on the Holweck-Lejay pendulum; the Marquet Prize to Gustave Ribaud, for his researches on high temperatures; the Alexandre Darrasq Prize to Etienne Audibert, Ferdinand Vallette and Francis Michot-Dupont (20,000 francs each), for methods of preparing petrol and benzene from materials obtained in France.

Prizes of the Grandes Ecoles.—The Laplace Prize to Robert Gachet; the L. E. Rivot Prize between Robert Gachet, Paul Cusset, Charles Mallet and Albert Jouvent.

General Foundations for Scientific Research.—The Gegner Foundation to the late Maurice Parat, for his work on the physiology of the cell; the Jérôme Ponti Foundation to Henri Besairie, for his work on the geology of Madagascar; the Hirn Foundation to Albert Arnulf, for his work in applied optics; the Henri Becquerel Foundation to Carl Benedicks, for his discoveries on the homogeneous thermoelectric effect.

(*To be continued.*)

Progressive Teaching in Geography

THE GEOGRAPHICAL ASSOCIATION

THE Annual Conference of the Geographical Association was held at the London School of Economics on January 5-7.

At the first lecture meeting, Dr. L. Dudley Stamp dealt with Portugal in 1936 and entered a plea for geographers to accord separate consideration to Spain and Portugal rather than to group the two together, which they frequently do, as the Iberian Peninsula. The cultural background and history so clearly demarcate the two that the visitor cannot help being struck by the differences, which indeed recent events have emphasized. By means of lantern slides the remarkable changes witnessed in a traverse from north to south were demonstrated, and a tentative division of the country was suggested into the north-west, the north-east, the middle Douro basin (the port-wine area), the coastal belt, north centre, south centre (these two separated by the Tagus), the southern Sierra, and the Algarve.

On January 6, Sir William Beveridge took the chair at an important symposium on "Whither Population?" in which Prof. C. B. Fawcett stressed the spatial distribution of the world's population, and Dr. R. R. Kuczynski the changing distribution in time. Prof. Fawcett demonstrated that modern development and migration are *not* filling up the empty spaces of the world but, on the contrary, the great cities are increasing relatively to the whole and the pioneer fringe is moving back. Even in densely populated Great Britain, rural depopulation has been in progress for many decades, and one-fifth of the land surface has more than fifty-eight per cent of the people (compared with fifty-one per cent ten years ago). In Canada, forty-two per cent of the people live on less than one per cent of the land; in the United States, more than fifty per cent on less than two per cent; in Australia, more than fifty per cent in the capital cities alone. Dr. Kuczynski developed his now well-known theory of population increase—that the true measure is the relation between women of child-bearing age and births of female children—between the mothers of to-day and the mothers of to-morrow. Where this net reproduction-rate falls below 1, the population must decrease. It is actually below 1 in all the countries of northern and western Europe, except the Irish Free State and Poland. It reaches its highest European figure now in the U.S.S.R. (more than 1·2). In Japan it is about 1·4. At present in Great Britain it is about 0·75, representing a decrease of one per cent per annum. The population at this rate will fall below 30 million by 2000 A.D. and below 20 million in 2036. As Sir

William Beveridge, in a masterly summary, pointed out, this may be desirable, but the process of change is bound to be painful. The arrest of the decline can be accomplished only slowly and in one way alone—by increasing the *desire* of the people to have children. Reference was made to existing tax concessions as being a bad joke or, alternatively, a penny in the pound towards the cost of child-rearing. It was suggested that serious State action has nowhere been attempted. The two great questions are thus: Do we want to stop the decline? If so, can we?

A valuable discussion was that on broadcast geography lessons, at which the teachers, the inspectors, the B.B.C., and broadcasters were represented. There was general agreement that systematic lessons should not be attempted, but that first-hand travel talks to be used as 'background' material, and accurate as well as useful and stimulating in content, should be the aim

Dr. H. A. Matthews detailed suggestions for the study of local climate and had some remarkable illustrations of local variations—the frost pockets by walls so well known to gardeners, the contrasts between the wind rose at the head of a valley (with one calm day per month and predominantly south-west winds) and at a village in the valley only one mile away (with fourteen calm days and the wind predominantly north-west or down the valley).

Mr G. H. J. Daysh summarized his very important recent work on Tyneside and the north-east, emphasizing two points specially—the contrast between the reviving water-side areas and the stagnant inland coal mining areas, and secondly, his own faith in emigration as the solution.

Mr. S. H. Beaver dealt with the scope of railway geography, and two meetings were devoted to joint sessions with the Leplay Society—with Dr. Stamp on Poland and Dr. L. R. Wood on Norway.

Sir Josiah Stamp's presidential address on "Geography and Economic Theory" can only be described as epoch-making in that it defined clearly, for the first time, the points of impact of two modern disciplines and has provided a gospel for future workers.

INSTITUTE OF BRITISH GEOGRAPHERS

The Institute of British Geographers held its annual meeting at the London School of Economics on January 6–7, Prof. R. N. Rudmose Brown replacing Prof. C. B. Fawcett in the presidential chair.

Mr. W. V. Lewis developed the theme of glacial plucking and corrie formation from the *bergschrund* hypothesis of Willard Johnson, stressing the importance of glacial sapping at the foot of corrie cliffs and the potency of summer melting Dr. S. W. Wooldridge considered the later stages in the physiographical evolution of the London Basin, thus continuing his well-known work published in the *Proceedings of the Geologists' Association*

Mr. F. H W. Green gave a succinct and well-illustrated account of the water-meadow systems of Hampshire; Mr. K. H. Huggins suggested a functional classification of English towns into five major groups: primary production, major industries, other industries, local services and regional services. Miss A. F. A. Mutton presented a detailed study of the Black Forest region and Mr. R. A. Pelham a study of the wool industry in the fourteenth century.

L. D. S

Mathematical Association

ANNUAL MEETING

THE annual meeting of the Mathematical Association was held at the Institute of Education, London, W.C.1, on January 4-5. At the business meeting, Prof. L. N. G. Filon was elected president for the ensuing year, and the officers were re-elected as follows: *Treasurer:* Mr. K. S Snell; *Secretaries:* Mr. G. L. Parsons and Miss M. Punnett; *Librarian:* Prof. E. H. Neville; *Editor of the Mathematical Gazette:* Mr. T. A. A Broadbent.

The report of the Council refers to the continued growth of the Association, which now numbers nearly 1,600. The library of the Association has been enriched by gifts from the Royal Technical College, Glasgow, and Mr C. O. Tuckey; also by an exchange effected by Prof. Neville with the Centre National de Documentation Pédagogique, Paris, as a result of which a very complete collection of French textbooks has been acquired. Reference is also made in the report to reviews of French and German text-books which have appeared in the *Mathematical Gazette*. The Teaching Committees announce that a supplementary report on the teaching of geometry will appear shortly and also that a sub-committee has been appointed to collect information about mathematical films The Association has become affiliated to the Conference of Educational Associations.

The outgoing president, Prof. A. R Forsyth, in his address entitled "Applied Mathematics in School Training: Some General Considerations", compared the standards demanded of an entrance scholar to Cambridge at the present time with those demanded sixty years ago. He noticed that, while there has been some modification of method rather than of matter in pure mathematics, applied mathematics is in a general way practically the same at the present day as it was when he himself was an undergraduate. This, he considers, is scarcely less than surprising, having regard to modern applications, and he went on to offer some general observations on the ways in which this defect might be rectified.

Prof Georg Wolff, of Dusseldorf, read a paper entitled "The Development of the Teaching of Geometry in Germany". He referred to the revolt against the traditional teaching of Euclid which occurred in England partly owing to the work of the A.I.G.T. (afterwards the Mathematical Association) and partly owing to the attacks of Prof. Perry and others. He outlined the phases of a similar revolt which took place in Germany, culminating in the report of the German Sub-Commission of the International Commission on the Teaching of Mathematics. In the newest developments of the subject (which date from

1925), he directed attention to the emphasis placed on descriptive geometry, especially on general topics of transformation such as orthogonal and point projection and perspective.

The proceedings of the second day opened with a discussion on the teaching of astronomy. Mr. J. A. Edgar outlined the work which might be done with boys up to lower sixth form level and gave valuable suggestions for practical work in constructing star maps, plotting the plane of the ecliptic and the measurement of time. Mr. R. L. Marshall directed attention to some dangers which, in his opinion, might attend the addition of astronomy to the curriculum, while Dr. L. E. Lefèvre urged the claims of astrophysics in the work done by science specialists, referring especially to the various results obtained by spectrum analysis. In the ensuing discussion, Mr. W. F. Bushell mentioned the importance of the alliance between geography and astronomy.

Dr. R. R. Kuczynski read a paper on "Population Trends". He explained that, while an adequate device for the measurement of mortality has long been known, a good method of measuring fertility has only recently been evolved. He showed how these two measures can be combined to give the 'reproduction-rate' of a population. He stated that if fertility and mortality remain as at present, the population of western and northern Europe appears likely to drop from 194 to 150 millions by the end of the century. The U.S.S.R. is apparently an exception, and the figures here suggest an increase from 175 to 650 millions. He concluded by warning his audience that a very clear distinction should be drawn between estimates meant as forecasts and estimates meant to show what, on certain definite assumptions, the population trend would be. The figures given were to be taken as belonging to the second of these categories.

Mr. R. M. Gabriel, in the next paper, urged the inclusion of the history of mathematics in the course of study both of schools and universities. Of the different methods of presenting the history of the subject, he preferred that which dealt with the history of various topics as they occur in mathematical work. He pointed out how the history of the subject serves to throw a light on the character of times and men (for example, Cardan and Tartaglia in relation to the Renaissance; Newton in relation to the seventeenth century). He instanced several mathematical types in which a knowledge of mathematical history would assist both teacher and pupil. In the course of a useful discussion, Sir Thomas Heath, Mr. A. W. Siddons, Prof. E. H. Neville, Mr. M Black and Mr. G. L. Parsons offered additional suggestions with regard to topics and bibliography.

In the afternoon, Dr. A. C. Aitken read a paper on "Arithmetical Recreations". He stated that his observations were really concerned with approximation, which will assume greater importance as mechanical devices for calculation are developed. After a preliminary discussion of the mental equipment needed by a good computer, Dr. Aitken demonstrated rapid methods of division and squaring, and as an illustration of his methods, squared several numbers of three and four digits mentally with great rapidity. He next showed how the periods of recurring decimals can be determined These methods of approximate evaluation of a square root were considered and their relative errors dismissed. Dr. Aitken concluded with some remarks on the nature of memory, in which he stressed the rhythmic element, illustrating this by writing down from memory the first two hundred figures in the value of π.

The concluding paper was given by Mr. A. Romney Green on "Geometrical Design". He commenced by describing the construction of certain polar curves and showed how these curves can be used for vases, brackets and other articles capable of being made in the school workshop. He also directed attention to the close conformity with Nature exhibited by certain leaf-designs derived from these curves. He next referred to the use of the conic (drawn as an envelope) and pointed out the superiority of these curves (used in Greek mouldings) over the circular mouldings in general use. The paper was illustrated by slides, including illustrations of pieces of furniture designed by the author.

In consequence of the indisposition of the president, Mr. A. W. Siddons presided over the meetings on the second day. The meetings were well attended throughout, and the usual publishers exhibition was held. A full account of the various papers will appear in the *Mathematical Gazette*.

Mechanized Farming*

OXFORD CONFERENCE

THE second Conference on Mechanized Farming was held in Rhodes House, Oxford, on January 5–8, under the auspices of the agricultural departments of the University, and attracted about 350 visitors.

The opening papers dealt with agricultural and technical problems arising from the extended use of tractors. An important technical problem arises from the use of paraffin rather than petrol as fuel. Under ordinary agricultural conditions, the use of the heavier fuel frequently results in rapid deterioration of lubricating oil, due to its dilution with unburned fuel components. In practice, therefore, the immediate economies which result from the use of paraffin are liable to be offset by increased consumption of lubricating oil, or, since farmers generally do not change the diluted oil often enough, by rapid wear of the engine. Measurements on tractors in the field and on test show that the solution of the difficulty is to maintain the temperature of the cooling water at as near boiling point as is practicable, to avoid changing over from the starting petrol to paraffin until a sufficiently high engine temperature has been reached, and to load the tractor as fully as possible.

---

* Papers can be obtained from the Institute for Research in Agricultural Engineering, University of Oxford, 1*s* 6*d*. post paid. A supplement embodying the informal discussions is to be published at a later date.

Another group of papers was concerned with cultivation problems. Mechanization offers so many opportunities of simplifying the traditional routine of cultivation, for example, by the use of rotary cultivators or trains of implements, that it becomes important to examine scientifically both the traditional treatments and the newer technique which may supplement them. Two papers described the work which is being done with this object at Rothamsted and Cambridge. It was suggested that certain tillage operations which are traditionally supposed to conserve soil moisture cannot be expected, in the light of modern theories of soil water movement, to exercise much direct control, although they may conserve soil moisture indirectly by removing the competition of weeds. Again, in statistical field experiments the ultimate effects of tillage operations on crop yields are frequently insignificant, although well-marked effects in soil structure can be demonstrated, for example, by the use of an instrument which automatically records the resistance to the penetration of the soil by a steel probe. Both papers concluded that traditional methods are liable to include many operations the utility of which is doubtful. This conclusion was criticized in another paper written from the farmer's point of view. It was suggested that the mental attitude of the experimenter towards cultivation operations is often at fault: that to regard the ultimate yield in a statistical experiment as the sole criterion is misleading: and that modern experimental technique is too rigid for the study of what may be considered as still an art.

Another paper opened a discussion on the maintenance of fertility, with particular reference to the part played by organic manures. It was suggested that the function of organic matter might appear less important as the science of tillage is developed and more is known about the application of such elements as boron, manganese and zinc. On the other hand, a better understanding of the part played by auxins, animal hormones and plant toxins might lead to a contrary conclusion.

Considerable interest was also aroused by several papers on grass-drying. These, however, were concerned more with questions arising from fitting the new process into farming routine than with drying technique.

Other subjects which received consideration at the Conference were equipment enabling tractors to be used for row crop work and recent developments in combine harvesting

Science News a Century Ago

The Analysis of Organic Compounds

"AT a meeting of the Medico-Botanical Society held on January 25, 1837, Mr Everett made some observations on the essential oil of almonds, the result of the examination of which by different continental chemists, led to the hope that the mathematical accuracy impressed upon inorganic compounds would soon be developed in organic compounds In the analysis of almonds, a substance called amygdaline was produced From this substance the German chemists have produced a liquid hydruet of benzoin, which by contact of atmospheric air, produces benzoic acid With this discovery, M Berzelius was so pleased as to suggest to MM Dumas and Leveque (to whom the scientific world is indebted for this information) to give it a name signifying 'Dawn of Day' or 'Orb of Day', illustrative of the new era which it opened in organic chemistry. M Mitscherlich, of Berlin, has also by the distillation of benzoic acid with quicklime, obtained an oily fluid identical with that procured in the condensation of oil gas, and described by Faraday as a liquid bi-carburetted hydrogen."—(*Athenæum*)

Structure of the Brain in Marsupial Animals

ON January 26, 1837, Richard Owen, Hunterian professor of anatomy to the Royal College of Surgeons, read a paper to the Royal Society "On the Structure of the Brain in Marsupial Animals". The official abstract of the paper said: "The author describes a remarkable modification in the commissural apparatus, apparently provided with a view to establish communication between the cerebral hemispheres, which he has observed in the brains of marsupial animals and which has hitherto been regarded as constituting the essential difference between the brains of oviparous and mammiferous vertebrata . . On comparing the structure of the brain in the Beaver and in the Wombat, he finds that the corpus callosum, or great commissure which unites the supraventricular masses of the hemispheres in the former, as well as in all other placentally developed mammalia, and which exist in addition to the fornix, or hippocampal commissure, is wholly absent in the latter animal: and that a similar deficiency exists in the brain of the Great and Bush Kangaroos, of the Vulpine Phalanger, of the Ursine and Mange's Dasyrus, and of the Virginian Opposum. . . ."

Cultivation of Rice in England

THE *Athenæum* of January 28, 1837, records the attempts of Mr. Anderson, the curator of the Apothecaries Garden at Chelsea, to cultivate mountain rice from Nepal, the experiment having been made to see whether it could be grown in Great Britain as an agricultural crop. The seed was sown in March in a hot-house and soon germinated. In May, when the seedlings were removed to the greenhouse, they had become stout healthy plants. At the end of June, they were transferred to a sheltered place in a basin for aquatic plants, having nine inches of water and twelve inches of mud They grew and promised well until the beginning of August, but the weather becoming cool they all sickened and died without flowering.

Medical Literature in 1836

"DURING the year 1836 there were published in France alone upwards of 300 volumes on the various branches of medical science. These 300 volumes, added to the numerous brochures, memoirs and other smaller tracts which have appeared, raise the quantity to 115,000 pages, which together with the journals and theses brought out at the same time render the total about 180,000 pages. Now should there be found a reader intrepid enough to undertake the perusal of all this, his monthly task must be to wade through nearly 16,000 pages, and his daily performance must be on the average 500. So much for French medical literature merely; add English, American, German, etc. !"—(*London Medical Gazette*, January 28, 1837)

University Events

Aberdeen.—The King has, on the recommendation of the Secretary of State for Scotland, approved the appointment of Prof. John Stirling Young, professor of pathology in the Queen's University, Belfast, to be regius professor of pathology, in succession to Prof. T. Shennan, who has resigned.

Cambridge.—D. V. Davies and Dr. W. R. M. Morton have been appointed University demonstrators in the Department of Anatomy.

At Gonville and Caius College, Prof. J. A. Ryle, regius professor of physic, has been elected into a professorial fellowship.

At Pembroke College, W. E. Burcham, Trinity Hall, has been elected into the Stokes studentship for research in physics. Mr. Burcham is engaged in research work in the Cavendish Laboratory.

At St. John's College, Prof. H. A. Harris, professor of anatomy, has been elected into a professorial fellowship.

London.—The Court of the University has accepted an offer of the Harry Price Library of Magical Literature to be on permanent loan in the University Library, and has passed a vote of thanks to Mr. Harry Price for the benefaction.

Dr. F. E. Zeuner has been appointed hon. lecturer in geochronology at the Institute of Archæology.

Societies and Academies

Paris

Academy of Sciences, December 28 (*C.R.*, 203, 1477–1556).

Louis Blaringhem: A new variety of *Zea Mays* with mahogany-coloured seeds.

Gabriel Bertrand and Lazare Silberstein: New researches on the comparative amounts of sulphur, phosphorus and nitrogen in plants cultivated on a given soil. Figures are given for fifteen species of plants. Exceptional results were obtained with celery: whilst in forty-six species of plants the ratio sulphur to phosphorus did not exceed 4·02, celery gave a ratio of 11·1.

Charles Poisson: Some magnetic rocks in the neighbourhood of Tananarive.

Alexandre Myller: The mean torsion of a surface.

Albert Edrei: Certain limit invariants of integral series.

Victor Lalan: Kinematics and the theory of groups.

Octav Onicescu: Physical laws expressed by statistical chains.

Georges Fournier: The upper limit of the atomic numbers. On the basis of certain geometrical assumptions, 136 would be the maximum atomic number.

Pierre Jolibois and Robert Bossuet: Some properties of a spark arising from the surface of an electrolyte connected to the negative pole.

Georges Costeanu and Pierre Barchewitz: The absorption spectrum of ammonia in the very near infra-red (6000 A.–9500 A.).

Jean Lecomte: Infra-red absorption spectra and the modes of vibration of organic compounds possessing an ethylene linkage.

Joseph Berthenod: Connexions by means of couplings with permanent slipping.

René Delaplace: The thermal conductivity of the gaseous saturated hydrocarbons at low pressure. Results for hydrogen, methane, ethane, propane, normal butane and isobutane are given as curves. For pressures between 0·001 mm. and 0·2 mm. of mercury, the homologues of methane have thermal conductivities increasing with their molecular weights.

Wilfried Heller: The slowing down of thixotropic solidification by the amino-acids.

Jean Chédin: The quantitative study of the intensity and the depolarization of some Raman lines emitted by sulphonitric mixtures.

Pierre Peyrot: Absolute measurement of the light diffused by liquid benzene.

Albert Portevin and Eugène Herzog: The action of various additions in small proportions on the marine corrosion of extra-mild steel. Results are given graphically of the effects of the presence of aluminium, chromium, nickel, silicon and phosphorus.

Paul Laffitte and André Parisot: The detonation of ammonium nitrate. Summary of results obtained by the photographic recorder method.

Louis Médard and François Déguillon: The Raman effect of some organic sulphur compounds.

Raymond Delaby: The βγ-ethylenic nitriles and some of their derivatives.

Léon Palfray, Sébastien Sabetay and Pierre Mastagli: The reducing action of benzylalcoholic potash and of sodium benzylate on aldehydes. Studies on three aldehydes of different type, cuminic, œnanthic and α-amylcinnamic aldehydes.

Gustave Vavon and Israel Chilouet: The structure of the menthylamines.

Albert Kirrmann and Robert Jacob: Study of the allyl transposition: a trichlorisobutene.

Robert Forrer: The intensity of the orbital interaction in salts The factor of the ions.

Mlle. Véra Malycheff: Contribution to the study of the soils of western Morocco. The brown soil formed at the expense of hamri.

Raymond Jouaust, Robert Bureau and Louis Eblé: The probable causes of the sudden fading of short radio-electric waves and their relation with magnetic phenomena. There is no evidence to connect these disappearances with magnetic storms.

Pierre Marie: The utilization of the Foraminifera in stratigraphy.

Robert Lemesle: The vessels with scalariform perforations of *Eupomatia* and their importance in the phylogeny of Polycarps.

Léon Bertin: A series of Leptocephalus belonging to the genus *Saccopharynx*.

Mme. Yvonne Khouvine, Boris Ephrussi and Morris Henry Harnly: The extraction and solubility of substances intervening in the pigmentation of *Drosophila melanogaster*.

André Kling and Guy Lecordier: The influence exerted by two war vesicants and by their products of hydrolysis on the values of the interfacial tensions of lipids towards physiological serum and on their absorption.

Mlle. Lise Emerique: Avitaminosis A and nitrogen metabolism.

Mme. Marguerite Aitoff: The transformations of the fermentation reactions of a dysenteric bacillus by passage through animals.

Max Aron: Serological researches on the nature of the principle contained in the urine of cancer patients.

Jean Cuillé and Paul Louis Chelle: Can the disease known as "tremblante du mouton" be inoculated? This disease is infectious and inoculable. The virus exists in the nerve centres.

Cape Town

Royal Society of South Africa, October 21.

G. D. B. de Villiers and **S. M. Naudé**: Effects of oil sprays on the transpiration of peach twigs. Oil sprays diminish the transpiration of twigs by about fifty per cent. Twigs sprayed with oil build up a greater reserve of sap than the unsprayed twigs. Hence when the buds open up, less danger exists of their drying out and the phenomena of delayed foliation and die-back occurring. Screening tends to decrease the transpiration in comparison with an unscreened tree Such trees, sheltered from the sun's rays in winter by screens or windbreaks, develop more normally than unsheltered trees.

I. Donen: Studies in deciduous fruit. (4) Distribution of nitrogenous fractions in the pulp of the Kelsey plum (*Prunus salicina*) Extracts of the nitrogenous fraction in the pulp of Kelsey plums were obtained by (*a*) water extraction of fresh tissue, (*b*) alcoholic extraction of frozen tissue, (*c*) expressing the juice, and (*d*) water extraction of pulp dried at 50° C. In young fruit, preservation of the tissue by freezing or drying resulted in hydrolysis of protein. In mature fruit the distribution of total soluble nitrogen, amide, amino acid and ammonia nitrogen, in the resulting extracts is not greatly affected by any of the methods of extraction used. (5) Preliminary observations on the relationship between nitrogenous metabolism and internal breakdown of Kelsey plums in cold store. Changes in the proportions of protein and non-protein nitrogen as well as changes in the ammonia, amino and amide nitrogen fractions in the flesh of Kelsey plums were followed by analysis of fruit stored at 35°, 50° and 70° F. Rapid hydrolysis of proteins takes place in plums under all conditions of storage, but the course of protein hydrolysis stops short at the amino-acid nitrogen stage. Conditions of maturity and storage which interfere with the course of progressive breakdown of nitrogenous compounds are also the conditions which interfere with the normal ripening of the fruit

W. E. Sharples: A Middle Stone Age site at Tygerberg, near Prince Albert.

T. A. Stephenson, A. Stephenson and **C. A. du Toit**: The South African inter-tidal zone in its relation to ocean currents. (1) A temperate Indian Ocean shore.

H. Zwarenstein: Experimental induction of ovulation (see Nature, Jan. 16, p. 112).

B. F. J. Schonland, D. B. Hodges and **H. Collens**: Combined oscillographic and camera studies of lightning. The leader process in all cases observed lowers a negative charge towards ground. The stepped leader involves an intermittent decrease of negative electric moment with corresponding radiation in the form of a ripple which always precedes the main radiation field caused during the return stroke. The dart leader process involves a continuous decrease in moment. Discharges taking place in a thundercloud are less important sources of atmospherics than those passing to ground.

Cracow

Polish Academy of Science and Letters, November 9.

M Petrovitch: Remark on the zeros of the Laplace-Abel integrals.

L Kozlowski: Kerr's electro-optical phenomenon in mixtures of nitrobenzene and hexane. For mixtures of low concentration, the relation between the Kerr coefficient and temperature is nearly linear. There is an anomaly in the region of the critical temperature of solution.

M. Centnerszwer and **M. Blumenthal.** (1) The thermal dissociation of lithium nitrate. Lithium nitrate, at a temperature above its melting point, decomposes into lithium nitrite and oxygen. The reaction is reversible, and the author has determined the Nernst equation. (2) The thermal dissociation of silver nitrate.

H. Liche: Observations on the behaviour of the Gerrides (heteropterous Hemiptera).

M. Bulawa: The lymphatics in the skin of the teleosteans.

Academy of Sciences (*C R.*, 4, No. 1; 1936).

W. Sierpinski: Semi-continuous functions.

P. P. Lazarev and **Z. V. Boulanova**: (1) The influence of muscular work on the adaptation in peripheric vision. (2) Changes in the peripheric visual adaptation in infants during a day.

P. P. Lazarev and **M. R. Semenovych**: Changes in the peripheric visual adaptation during a year.

A. Obručeva and **A. Frumkin**: Attainment of a potential by platinum in solutions of silver salts.

I. A. Goljanickij and **I. S. Belonosov**: Reduction of the inactivated *l*-ascorbic acid.

O. S. Vialov: Classification of oysters (*Ostreinae*).

A. S. Serebrovskij: Second variant of the M-σ^2-triangle method.

E. Šestakov and **L. I. Sergeev**: Changes in the permeability of protoplasm and the dynamics of frost resistance of winter cereals in connexion with their passage through the light stage.

E. G. Andreeva: The proportions of the leg bones of some *Bovinae*.

A. J. Bazikalova: A new form of Amphipoda from Lake Baikal (*Gammarosphaera insularis*, gen. et sp. n.).

Vienna

Academy of Sciences, October 29.

Stefan Meyer: Possible existence of an isotope of polonium in the thorium series.

Erich Tschermak-Seysenegg: True, derived, and doubtful wheat-rye hybrids (wheat-like forms).

Rudolf Inzinger: Infinitesimal geometry of contact transformations.

W. J. Muller: Theory of metal potentials (1).

L Kahovec and **A. W Reitz**: Studies of the Raman effect (61). Raman spectra of organic substances (benzene derivatives).

November 5.

Otto Ampferer. Were the Alps unglaciated between the Wurm and the final glacial periods ?

Zora Klas: *Thiosiphon*, a new species of sulphur bacterium

Franz Urbach and **Helene Schlesinger**: Mechanical and acoustical tests of pianofortes.

Anton Kailan and **Walter Melzer**: Influence of neutral salts on velocity of esterification and viscosity in solutions of hydrochloric acid in ethyl alcohol.

Max Toperczer: The earthquake at Obdach on October 3, 1936

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, January 25

University College, London, at 5.—Dr. H. R. Ing: "Chemical Structure and Pharmacological Action" (Succeeding lectures on February 1, 8, 15, 22 and March 1.)*

Institute of Actuaries, at 5.—F. J. C. Honey: "The Estimated Population of Great Britain, 1941–1971".

Bedford College for Women, at 5.15.—Prof. R. F. A. Hoernlé: "Theory of Knowledge". (Succeeding lecture on January 26.)*

London School of Hygiene and Tropical Medicine, at 5.30.—Prof. W. Bullock, F.R.S.: "The Development of Bacteriology with an Account of some of the Pioneers who made it a Science" (Heath Clark Lectures. Succeeding lectures on January 28 and February 1, 4 and 8).*

Royal Geographical Society, at 8.30.—A. R Glen: "Northeast Land, 1935–36".

Wednesday, January 27

Royal Society of Arts, at 8.—J. T. Randall. "Luminescence and its Applications".

Thursday, January 28

King's College, London, at 5.30.—Arthur Gardner: "English Mediæval Sculpture". (Succeeding lectures on February 11 and 25, and March 11.)*

Friday, January 29

Geophysical Discussion, at 4.30.—(at the Royal Astronomical Society).—Discussion on: "Terrestrial Heights" to be opened by Dr. J. de Graaff Hunter, F.R.S.

North East Coast Institution of Engineers and Shipbuilders, at 7.—Prof. A. L. Mellanby: "Land and Marine Steam Generators, with Particular Reference to Future Developments" (Andrew Laing Lecture).

Royal Institution, at 9.—Sir William Bragg, F.R.S.: "Recent Crystallography".

Saturday, January 30

British Mycological Society, at 11.—(at University College, Gower Street, London, W.C.1).—Symposium and Discussion on "Antagonism of Micro-organisms" to be opened by G. Samuel.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Civil Engineer in the Rangoon Development Trust—Messrs Binnie, Deacon and Gourley, Artillery House, Artillery Row, London, S.W.1 (January 27)

Two Assistant Chemists for the London Shellac Research Bureau—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (January 30).

Assistant Guide-Lecturer (archæology and natural history) in the Leicester Museum and Art Gallery—The Director (February 10).

Professor of Zoology in the University of Cambridge—The Vice-Chancellor (February 26).

Professor of Physiology in the University of Cambridge—The Vice-Chancellor (March 4).

Professor of Geology in the University of Oxford—The Registrar (March 6).

Professor of Social Anthropology in the University of Cambridge—The Vice-Chancellor (March 9).

Assistant Director of Metallurgical Research in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 88a Gower Street, London, W.C.1

Native Races and Nationalism in Africa

THE development of nationalist ideas as an effective political force in eastern Asia and, more particularly, in India, has afforded a justification for those who hold that a like course of events may be anticipated sooner or later among the native races of Africa. Negro Africa, that is, Africa south of the Sahara, they would maintain, is an unsurpassed forcing house for ideas such as have inspired the more loudly vocal element in recent and current political agitation in India. For these regions of Africa are the meeting-place of two utterly diverse races, white and black, who are poles apart in physical character, mental outlook, tradition and culture, and of whom, while one, everywhere numerically the inferior, is politically and economically dominant, the other is rapidly transcending the limitations as well as outgrowing the opportunities of tribal code and indigenous culture. The natural division thus existing in the community, and reinforced by social and political barriers, must inevitably, it is held, give rise to a group consciousness on the part of native peoples, which unless checked or diverted, will tend to the more unstable and politically dangerous forms of racialism and nationalistic ideation.

Fortunately, diagnosis of possibilities in the trend of the development of native outlook is not entirely a matter of speculation. In Africa south of the Zambezi, where conditions are most favourable to the rise of nationalism, the Union of South Africa has for a guide in its approach to the native question experience of native reaction to a variety of European contacts extending over a long period of time; while the mining industry for nearly half a century has brought native administration into contact with the problems which arise out of the employment of labour on a large scale. But we may go even a stage further than general considerations, which emerge from an investigation of past history, and lay our finger on specific movements and events of recent occurrence pointing in the direction of an emergence of a sense of the solidarity of native interests, which if racial rather than national in character, is none the less significant of growth towards a feeling of community and of the power of a common direction in action and sentiment. This at least would appear to be the salient lesson to be learned from the valuable survey of recent happenings and tendencies in South, East, and West Africa, given by Lord Hailey in his address on "Nationalism in Africa" before the Royal Empire Society on January 19, when he summarized his study of the situation, as well as the results of observations made on his recent tour through Africa. His conclusions were the more worthy of careful note, since he was at pains to point out that while well aware of the opinion which views, not without alarm, the possible trend of development in native African political opinion towards nationalism, he himself is not among the prophets, but merely records as an observer.

In another matter Lord Hailey had taken his stand with no little wisdom. He refrained from any attempt to define nationalism, assuming that the character of this political and economic attitude or doctrine was sufficiently familiar to his audience to need no definition; but he indicated that he meant by 'nationalism' the governing force of a uniting will directed to national advancement in combination with certain social and economic factors, such as had manifested itself in European history during the period beginning in the eighteenth century and had appeared recently in Asia. Taking advantage of this elasticity in his point of view, he was able to bring under consideration aspects of native activity which on a stricter interpretation of the term might have to be excluded, and while admitting variety in the meaning of 'nationalism', enabled him to seek for such evidence as would indicate that native self-consciousness was becoming an "effective factor"—a new phenomenon, creating a new problem. Hence, as he pointed out, it is not merely opposition to Government that gives a movement significance in this sense, but rather such events as would testify to the growth of racial feeling or afford proof that the natives of different tribes or areas could combine on a common basis. For such an exhibition of growing consciousness it is natural to look to circumstances in which the material factor is more prominent, as for example in the curtailment of land, or the creation of unequal economic conditions. In taking, therefore, the Union of South Africa as his natural starting point, Lord Hailey is in accord with the view that the occasion and opportunity for the development of nationalism will most probably be found south of the Zambezi.

Before passing on to note some of the more important events and tendencies, to which in Lord Hailey's opinion this special significance may be attached, it is perhaps worth while to point out that whereas the white population of the Union of South Africa is determined at all costs to protect from native intrusion the white civilization which has been built up there, the native population, on its side, at least in so far as represented by the more thoughtful and influential of its leaders, is equally convinced that segregation and conservation of the elements of native solidarity is fully as necessary for the well-being of the native community. It is from the promoters of this movement and from this line of thought that nationalism in South Africa, if or when it comes, will draw its strength. On the other hand, in the labour movements to which Lord Hailey referred, it is perhaps not so much racial feeling as the colour bar which has been operative. The two are by no means identical; and in view of the wide area and varied tribal units from which recruits are drawn, labour perhaps has been often of too heterogeneous a character to warrant it being regarded as of great significance in a racial sense, although naturally of evidential value in relation to the ability of the native to combine.

It was this heterogeneity, perhaps, as much as any single factor, which led to the collapse of the famous (or infamous) Industrial and Commerical Union, which was initiated under Soviet influence and at one time numbered 250,000 members. Nevertheless, it has to be remembered that it was held by those who investigated the movement officially after the riots at Port Elizabeth in 1922 that it did afford some evidence of Bantu racial consciousness. The members, however, were either detribalized, or not at the moment under tribal control, the mine labour, numerically the most important, being, as already mentioned, recruited from tribes at a distance. It is also to be noted in this connexion that in East Africa such trouble as has occurred from time to time in riots at Nairobi and elsewhere, as a rule, has been caused for the most part by detribalized natives. Except under abnormal conditions, tribal institutions favour the settled order. This is a fact which should not be overlooked in estimating the character and motives of movements which appear to lead in the direction of nationalism.

Of the circumstances affecting the solidarity of the native communities in the Union, by far the most important has been the question of land. It touched every member of tribal and rural community alike. As vital to native existence, it unified Bantu opinion throughout the Union in a common cause and to a degree scarcely witnessed before if at all. So far back as 1913, when Botha's land legislation was introduced into Parliament, this question was responsible for the formation of the short-lived African National Congress. It endured as a source of unrest until further legislation in 1936, when the question was complicated by the proposal, which was carried, to abolish the Cape Franchise, the restricted but highly valued native vote. Although, as Lord Hailey points out, this in itself produced no lasting effect or permanent organization, it did much to promote unity by bringing together members of the native races for discussion and protest with a common aim. An African convention in 1935 set up an organization to achieve reforms by constitutional means, but it is too soon to pronounce on its merits.

While Lord Hailey does not appear disposed to attach too great weight to the movement towards Separatist Churches, such movements are frequently an outlet, sometimes a source and inspiration, for nationalist movements of a formidable character. One of the most serious difficulties of the Kenya administration which assumed something like nationalist proportions was the Kikuyu female circumcision controversy.

A brief reference to conditions in other parts of Africa must suffice. In East Africa, circumstances not unlike those of South Africa, though on much smaller scale, have produced similar reactions in the formation of associations for the advancement and formulation of native interests. In the older colonies of West Africa, the education of natives on European lines has produced an intellectual class which seeks wider recognition of native rights through existing constitutional means. Nor is it necessary that the French and Belgian colonial empires should detain us, for in the former, as Lord Hailey points out, everything is directed to France—an orientation which finds expression in the representation of colonial interests in the legislature of the mother country by a native deputy; while under Belgian rule, both in the colony and the mandated territory, commercial rather than political development of native resources is the aim Lord Hailey might perhaps have added that under French rule, in actual practice something very much in the nature of the indirect rule of the British dependencies is the result.

In pursuit of his intention to act as an observer only, Lord Hailey, while noting that the trend towards the nationalist idea is approved by some, but strongly condemned by others, made no attempt to sit in judgment. Nevertheless, the question is one that will be posed by the mere efflux of time, and insistently will demand an answer. It will have been noted that the movements to which attention has been directed have all been separatist in character. They have emphasized the fission in the community, which results from the association of black and white. Is this inevitable? This raises a large question, which involves the whole future of the African races. It is obvious that neither under the policy of indirect rule nor of segregation, as in South Africa, will the African peoples stand still. The rapid advances of the last few years are a sufficient negation of any such conception. It is the belief of those who hold to the advantages of indirect rule, as well as of those who see the possibilities of advance under other systems, that the future of Africa lies in the co-operation of the two races. For this, and to determine the lines upon which it should be pursued, the assistance of the more advanced and intellectual members of the African peoples must be secured. If, as many think, the movement towards racial or national self-consciousness is an inevitable phase of development in Africa, time should be taken by the forelock, and this force, great as it must and will be, should be harnessed to the constructive task of building up a united community, rather than weakening the social structure of Africa by setting a gulf between the elements which should co-operate.

Unsolved Soil Problems

Fifty Years of Field Experiments at the Woburn Experimental Station

By Sir E. John Russell and Dr. J A. Voelcker; with a Statistical Report by W G. Cochran. (Rothamsted Monographs on Agricultural Science) Pp. xvi +392 +4 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 21*s*. net.

CROP husbandry, the first occupation of man, which must ever remain essential to the maintenance of human life, has been pursued through all the ages as an art and a craft. The bearing of science upon it is a very recent development which is probably still only in its initial stages. Crops grow in vital association with two media, the air and the soil. It is barely a century ago that, following the discovery of photosynthesis, the main facts about the relationship of the crop to the air became generally known. The essential facts about the relationship of the crop to the soil are still clouded in mystery. In spite of all the development in the study of plants on one hand and of soils on the other, very little is known of the relationship of one to the other, and we are still largely dependent upon empirical experiments in order to determine the effect upon the plant of any particular treatment of the soil. Moreover, as this account of the Woburn experiments shows very clearly, the successful conduct of empirical experiments is beset with great difficulties.

Field experiments to test the effect upon the crop of applications to the soil began about a century ago with the work of Boussingault in France. The now classical Rothamsted experiments were commenced shortly after, and in 1876 the Woburn Experimental Station was commenced by the Royal Agricultural Society on land given for the purpose by the Duke of Bedford. The Woburn Station was originally designed to deal with the specific problem of determining the increased value of animal manure following the feeding of concentrated food. Prior to the beginning of these experiments, it had been the practice in many districts for an incoming tenant to compensate the outgoing tenant for that part of the money spent upon concentrated foods which was deemed to have passed to the manure and which therefore became the property of the incoming tenant. The passing of the Agricultural Holdings Act in 1875 made such compensation compulsory. J. B. Lawes, moreover, had for some time previously been concerned with the fact that there was no scientific basis for assessing the residual manurial value of feeding stuffs, and he gave invaluable assistance in the initiation of the Woburn scheme. A number of other field experiments were started at Woburn, and their progress over fifty years is reviewed in this book.

The story of the experiments is in a sense three times told in this book In the first part Dr. Voelcker, who succeeded his father as the Director of the Woburn Station, gives a categorical account of the work. In the second part Mr. W. G. Cochran gives a statistical examination of the results, and in the third part Sir John Russell summarizes the results in their bearing upon agriculture.

A first reading of an account of the Woburn experiments is disappointing, and in a certain sense this book is the story of failures. This sense of disappointment and of apparent failure arises, however, from the fact that many of the experiments at Woburn have not given the results that were anticipated, and the real value of the book lies in a full consideration of that fact. The residual manurial experiment which dominated the beginning of the Woburn work was designed to compare the effects of feeding cotton cake containing 6·6 per cent nitrogen and maize meal containing only 1·7 per cent, but whether fed to bullocks under cover or sheep folded on the land, there ensued no evidence of the superiority of the cake over the corn, and the result is frankly admitted by the authors to be both disappointing and mysterious. The ploughing-in of green manure has figured prominently in the experiments, and the results suggest that green manuring and the ploughing-in of legumes are by no means certain to benefit a succeeding wheat crop.

The Woburn experiments, however, have by no means all led to negative results. From the beginning there have been continuous barley and wheat plots, differently manured on a plan not unlike that of the classical experiments at Rothamsted. These plots have been valuable in confirming the chief findings of the Rothamsted plots.

The outstanding result of the continuous barley experiments at Woburn is the development of acidity in the soil following the continuous application of ammonium sulphate. This has resulted in a complete failure of the barley crop. The oxidation of the ammonium radical to nitric acid means that an application of ammonium sulphate is virtually an application of sulphuric and nitric acids, and the Woburn plots will always remain the classical demonstration of this fact. The effect has not been seen at Rothamsted because of the relatively large supply of calcium carbonate in the soil. Sir John Russell rightly says that in the whole range of British field experiments there has probably been nothing more striking than this effect of ammonium sulphate on the Woburn barley.

One great lesson from the book under notice as a whole is the fact that the conduct of field experiments is by no means the straightforward procedure that it was thought to be at the time the Woburn experiments began. The necessity for statistical treatment of results was not thought of in those days, and consequently, even in the continuous barley and wheat experiments, the design of the experiment has been such as to limit what the statistician can do with the results. This is a fact which is fully admitted by the authors, who also point out that another lesson from these experiments is that, once a continuous experiment has been designed, modifications at a later date should be avoided. The results of the barley and wheat experiments would have yielded more to the statistician if it had not been for changes in the scheme of manuring.

The supreme difficulty in field experiments, which has led to the modern methods of design giving results that can be dealt with statistically, is the variation of soil. Apart from certain warp soils, there is almost certainly no such thing as a soil that is uniform either horizontally or vertically. The Woburn soils seem to be particularly unfortunate in their variation. A section on the soils at Woburn is contributed by Dr. E. M. Crowther. It gives an account of the effect of the treatments upon the organic matter and exchangeable bases and will be read with much interest by soil chemists. The soil is a light sandy loam derived from drift overlying Lower Greensand. The variations are particularly marked in the subsoil.

Everyone interested in field experiments will be grateful for this book and for both the positive and the negative results of the Woburn experiments. They each have their value, and whatever may be the future of Woburn, the work already carried out there will certainly remain classical.

Thirty Years for the Public Health

The Last Thirty Years in Public Health: Recollections and Reflections on my Official and Post-Official Life. By Sir Arthur Newsholme. Pp. 410 +13 plates. (London: George Allen and Unwin, Ltd., 1936.) 15s net.

TO the many who read, enjoyed and appreciated the first volume of reminiscences of Sir Arthur Newsholme, published a little time ago under the title of "Fifty Years in Public Health", the appearance of this second instalment of what he calls his "Recollections and Reflections on my Official and Post-Official Life" will be much welcomed. Both volumes are written with enthusiasm, which is not at all surprising since they have reference exclusively to activities in the field of public health, and from the day he entered it until this very moment, it is probable that there has been nothing that Sir Arthur has been so enthusiastic about as public health. Public health administration, public health progress, public health organization—these, it is safe to believe, since there are his works—this and a multitude of others—for evidence, have been, in effect, his unique concern Probably it is because of this that his career has been so successful.

It is because of it that these two books—that of fifty years and this of thirty years—have so much of value: not only immediately, to those of this and Newsholme's own generation of health workers, but also historically as well. As a matter of fact, so very unwilling has Sir Arthur been to devote space to references to himself, his own life and activities, and so anxious to refer to the public health problems that were tackled and the schemes that were evolved during the period of which he writes, that in spite of what he himself says, it is much more of a historical than a personal document he has produced.

The years with which in this present volume Sir Arthur deals are those from 1908 to the present. In the volume he divides the period into two—the first, 1908–1919, when he was, as he claims, "at the head of the Medical Department of the State's Central Health Organisation"; the second from 1919 to the time of writing, when, though he seems to have worked very hard, he had opportunities at any rate for having a much more interesting time than ever before, whether at Brighton, as the greatly trusted Medical Officer of Health, or at Whitehall as the immediate successor of Sir William Power and in the line of giants like Sir John Simon, Sir George Buchanan and Sir Richard Thorne Thorne.

That Sir Arthur was really happy following his transplantation from Brighton to Whitehall may be doubted. What he has to say here and there in Part 1 of the volume under the heading "Official Life in Whitehall" does not convince that he was. Since while Medical Officer of the Local Government Board—which preceded and was absorbed by the Ministry of Health—he was able to see launched schemes in which he had for long been deeply interested, it might have been supposed that there was real reason for happiness Among matters on which he had written and spoken much and also attempted to set moving long before he left local for central administrative circles were tuberculosis and venereal disease control and infant and child welfare. During his period of service at Whitehall, schemes in regard to these were well established, or the ground at least was well prepared for their establishment. Similarly, it should be remembered, and in the volume there is included, very properly, a reminder, that it was very largely due to the efforts of Newsholme that there was recognition of the need for securing that both on behalf of the child and of the mother herself greater attention should be given to motherhood and to maternal welfare. It is in Part 1 of the volume that Sir Arthur deals with matters such as these and the years 1908–19, that he spent at Whitehall. That there is very much more that he would like to say of this period is very clear.

At the same time, however, there is more than a hint that there was much more that he would have liked to have got done and some things that perhaps he would have liked to have seen done in a different way. Also there is full evidence that the part he played in the progress made was one of extreme importance.

The remaining parts of the book reveal mainly that while at the head of the Government Health Department Sir Arthur added vastly to the already great reputation he enjoyed throughout the world of public health Under the headings "Recollections of American Public Health and Social Work" and "The Increasing Socialisation of Medicine", he shows that instead of passing into retirement on the day he left Whitehall, actually he entered upon a new phase of his career. From a variety of directions came invitations and demands for assistance, guidance and advice. Acceptance of these invitations and the meeting of these demands, the record indicates, caused him to make or renew contacts all over the world, but more particularly in the United States, and brought him, it cannot be doubted, a wonderful new measure of happiness.

In the American chapters Sir Arthur tells of the years spent at Baltimore as lecturer in the School of Hygiene of Johns Hopkins University. He gives also much interesting and valuable information with regard to public health administration in the United States and makes generous reference to American achievements in public health and tropical medicine.

In the third and final part of the book, which Sir Arthur devotes to a discussion of the increasing socialization of medicine, he has again much to say of things American. Probably, however, the most interesting chapters in this part are those relating to the visit paid to Soviet Russia in 1933. To an extent in these he fills in gaps left in the description given in another book of his, "Red Medicine; Socialised Health in Soviet Russia", written in collaboration with Dr. J. A. Kingsbury, at that time secretary of the Milbank Fund. Obviously what he saw in Russia impressed him, though not always favourably. He recognizes, however, the value attached to the social work now in progress in that country, and believes that developments even more valuable, from some of which the nations as a whole may have something to learn, are certain to take place.

As a matter of fact, these would appear to be the conclusions that in general Sir Arthur would wish to have drawn from what he has written in this book and its predecessor. In his life-time, he finds, almost incredible advances have been made, with unparalleled additions to human knowledge, that, having been applied, have resulted in profound improvement in the health and living conditions of the people as a whole. Great as has been the progress and the improvement, however, he still believes in the possibility of advances even greater and more important—believes, indeed, that the best is still to come.

An indefatigable worker and possessed of an enthusiasm for public health that has never flagged, the contributions that Sir Arthur himself has made to the progress that the past has shown and that the future holds are vast. It is good that he has written this book about these things. It has great value and great interest not only for those engaged or concerned in health work, but also for the more general reader.

Diesel Engineering

(1) Elements of Diesel Engineering: an Introductory Manual easily understood, covering the whole field of Design, Working, Maintenance and Repair of Stationary, Marine, Aircraft and Road-Transport Types of Diesel Engines. By Orville Adams. Pp. xvi+478. (London: Constable and Co., Ltd., 1936.) 18*s*. net.

(2) Diesel and other Internal-Combustion Engines: a Practical Text on the Development, Principles of Operation, Construction, Details and Performance of Stationary and Portable Diesel, Gas and Gasoline Engines. By Prof. Howard E. Degler. Pp. vii+237+5. (Chicago: American Technical Society; London: Crosby Lockwood and Son, Ltd., 1935.) 10*s*. 6*d*. net.

(3) Diesel Engines: Excessive Lubricating Oil Consumption. By P. H. Smith. Pp. ix+85. (London: Constable and Co., Ltd., 1935.) 3*s*. 6*d*. net.

IN addition to publications arising from its importance from scientific, technical and commercial points of view, the Diesel engine has to a quite considerable extent encouraged the production of books suitable for the instruction of drivers and others whose livelihood may depend on a broad, though not necessarily deep, knowledge of its principles, details and operation. The need for this class of book arises, to some degree, from the restriction of the practical training given to those placed in charge of machinery, more particularly that used for transport.

(1) It is expressly in order to assist the practical man in this position as well as to enlarge the field of view of the engineering student, and to help both to a fuller understanding of the operation and working principles of the Diesel engine, that "Elements of Diesel Engineering" has been written. The development and application of this type of engine are recognized in America as offering the most promising future for the mechanically-minded young man, and large numbers of students have come forward to prepare themselves to take advantage of these possibilities. While to the trained engineer there is a strong family resemblance between the various internal combustion engines, and differences in detail are readily recognizable as functional, the change from one cycle of operations to another, from one system of fuel supply to another, or from a familiar to a new method of ignition involves for the average driver a complete break with the tradition to which he has become accustomed.

This introductory manual, written in non-technical language, offers practical information of a descriptive and critical nature as to the construction, operation and maintenance of the Diesel engine and discusses the main features of its various parts and the qualities and properties of suitable fuels and lubricants. Although thermodynamics is not dealt with, the thermal principles are explained and mechanical theory also receives attention. Of great value are the numerous illustrations, which are clear and well produced.

(2) In the same category may be mentioned "Diesel and other Internal-Combustion Engines" which has been prepared with a similar end in view. In smaller scope it deals with all the types and gives more prominence to thermodynamic and other theory, but in an explanatory rather than an analytical manner.

(3) In a virile little book, Mr. Philip H. Smith, out of his wide experience as inspecting engineer to Lloyd's underwriters, deals with the excessive consumption of lubricant which characterizes the Diesel engine. The remedies and palliatives which he recommends as having been tried and proved effective are for application to engines in service; but his remarks and conclusions are worthy of the closest attention by designers, who have the greater opportunity of developing them under favourable conditions.

The sphere of the Diesel engine was described in a lecture last year to the Royal Society of Arts by G. Mackenzie Junner, editor of the *Commercial Motor*, entitled "The Oil Engine and its Influence on Road, Rail and Air Transport" (*J. Roy. Soc. Arts*, July 24, 1936). On the road, owing to its greater cost, the Diesel engine is advantageous over the petrol engine only in cases of heavy loads or long mileage. In rail transport it has to compete with its very economical rival the steam engine, but the author can point to notable advantages in that it is immediately available when wanted and can be shut down with equal promptitude, thus saving wages and fuel costs preparatory to and following the period of useful operation. In the air its merits, though as yet far from fully developed or manifested, lie in its less inflammable and less volatile fuel, in the absence of sensitive carburetters and ignition systems and in its immediate readiness for service without a prolonged period of warming up. Of these three spheres of employment, the paper offers a general survey of considerable interest.

A New Natural History

Natural History
Edited by Dr. Charles Tate Regan. Pp. 896 + 16 plates. (London and Melbourne: Ward, Lock and Co., Ltd., 1936.) 25*s*. net.

DR. TATE REGAN is to be congratulated on having succeeded in giving the student and the intelligent reading public a really well-balanced and accurate account of zoological natural history in one volume of less than a thousand pages. He is fortunate in having as his collaborators a panel of experts, each of whom is an acknowledged authority on the subject with which he is concerned. He himself deals with fishes; mammals are in the safe hands of Mr. R. I. Pocock; Mr. W. B. Alexander, of Oxford, is responsible for the bird section and Mr. E. G. Boulenger, director of the Aquarium at the London Zoo, for reptiles and amphibians, while invertebrates are split into insects and those other than insects, and are dealt with by Miss D. Aubertin and Mr. G. C. Robson respectively. A systematic arrangement of sections has been adhered to by each author, which makes the whole an easy book of reference.

The most modern system of classification has been applied in every case and it will doubtless come as a shock to many readers to find, for example, that such old and familiar friends as the lion, tiger, leopard and jaguar no longer belong to the genus *Felis* but have been translated to a new and very select genus *Panthera*, while several of the other cats such as the so-called clouded leopard and the serval have been exalted to entirely new genera. Each section has a useful introductory chapter which deals with the main attributes of the order concerned and also with related forms which have become extinct.

Apart from the letterpress, which meets both the needs of the general reader and the serious student, the volume is illustrated throughout with a collection of more than a thousand photographs of, in most cases, living animals taken by expert animal photographers in Nature and in zoos all over the world. In addition, there is a number of coloured plates reproduced from pictures by famous animal artists. Here is indeed a book of great scientific accuracy and detail which also has a popular appeal and which at the price is highly concentrated value. G. M. V.

Manual of Public Health:

Laboratory Practice. By Prof. J. R. Currie and contributors. Pp. xix+378. (Edinburgh: E. and S. Livingstone, 1936.) 21*s*.

It is an ambitious project to attempt to survey the whole of laboratory practice appertaining to public health in one volume, including as it does such varied subjects as chemistry, bacteriology, protozoology, helminthology, entomology and meteorology, but on the whole we think the author and his collaborators have succeeded.

The sections on protozoology, helminthology and entomology are excellent, and the respective authors, Dr. Staig, Miss Jepps and Dr. Mears, have written adequate summaries, as completely up-to-date as could be expected in subjects which are in a state of flux, and the numerous illustrations, many of which are original, increase the value of these sections. In meteorology, all the essential subjects appear to have been dealt with. In the introduction, it is suggested that the medical officer of health should be reasonably well informed on public health chemistry, and the section on chemistry conveys, we think, sufficient information to ensure this. The description of the quantitative test for benzoic acid does not, perhaps, mention all the precautions necessary, and the Werner Schmidt method for fat in milk might have been dealt with in less cumbersome form.

The section on bacteriology is the weakest in the book and is very 'sketchy', though the author to some extent disarms criticism by stating that a preliminary training in the subject is assumed, and the purpose of the article is to show how to get under way with the procedure required. Some of the details of the Rideal-Walker test of disinfectants are inaccurate, and under 'water' it would have to be almost sewage to show the presence of *Cl. welchii* in so small a quantity as 5 c.c.

The book is well produced, has adequate and excellent illustrations throughout, and a good index.

Great Earthquakes

By Dr. Charles Davison. Pp. xii+286+12 plates. (London: Thomas Murby and Co., 1936.) 17*s*. 6*d* net.

This volume may be regarded as a sequel to the author's monograph, "The Japanese Earthquake of 1923" (1931), about the great Japanese earthquake of September of that year. Eighteen other important earthquakes of the last two centuries are now described. Most of the shocks caused serious loss of life and extensive damage, but the selection is primarily of those which have been investigated in such detail that the results are of value towards an understanding of the nature and origin of great earthquakes.

The earliest shock of the series is the Lisbon earthquake of November 1, 1755, in which the greater part of the city was destroyed and the loss of life ran into tens of thousands; the latest is the shock off the Sanriku coast of Japan on March 3, 1933, when more than three thousand people were drowned by the sea-waves due to the earthquake. Among the best known of the other shocks are the Mino-Owari (Japanese) earthquake of 1891, the Assam earthquake of 1897, the San Francisco earthquake of 1906, the Italian earthquake on December 28, 1908, in which Messina and Reggio were destroyed, and the Hawke's Bay (New Zealand) earthquake in February 1931.

For each earthquake are given details of the nature and effects of the shock in the surrounding regions, of the loss of life and material damage, of the earth movements and other phenomena accompanying the disturbance, and descriptions of the aftershocks. The geographical distribution of the intensity is generally shown by maps of the isoseismal lines. The seismic history of the various regions is a valuable feature, having been prepared from works which are not easily accessible.

The Annual of the British School at Athens

No. 34: Session 1933–1934. Pp. ix+198+49 plates. (London: Macmillan and Co., Ltd., 1936.) 50*s*. net.

The thirty-fourth issue of the "Annual of the British School of Archæology at Athens" differs from its predecessors in omitting formal matter and the useful annual review of archæology in Greece by the Director which have appeared in these volumes hitherto In future this material will be issued separately to subscribers to the funds of the School. The present volume, therefore, contains only papers, two in number, by members of the School. Mr. R. F. Cook discusses "Fikellura Pottery"—a group of ceramics, possibly better known under the name "Samian", which is not adopted here for good and sufficient reasons, as set out by the author. The second paper is on "Lakonian Vase Painting" by Mr. E. A. Lane. It carries further and adds to the study of material which has previously been the subject of investigation by a former member of the School, Prof. J. P. Droop, to whose conclusions, more especially in chronology, alternative suggestions are sometimes made. Both papers are very fully and admirably illustrated.

The B.D.H. Book of Reagents for 'Spot' Tests and Delicate Analysis

Fifth and enlarged edition. Pp. viii+96. (London: British Drug Houses, Ltd., 1936.) 2*s*. 6*d*.

The latest developments of chemical analysis have led to a demand for spot tests which can be carried out quickly and in large numbers and afford direct evidence of the presence of minute traces of various substances. The reagents are all organic substances. In this monograph these substances are listed, together with the elements for which they are agents. A selection, seventy-one in number, has been made from the many which have been proposed after careful trial in the B.D.H. laboratories. It is believed that all these reagents are now made in Great Britain, a testimony to the success of the Safeguarding of Industries Act. Each test is described in sufficient detail with references to the original literature: many of them are of quite extraordinary delicacy.

The Field of Clinical Science

LORD NUFFIELD'S GIFTS TO OXFORD

By Prof. T. R. Elliott, C.B.E., F.R.S.

MEDICINE as a charity for the sick poor has for hundreds of years been entrusted with the gifts of kindly minded men and women. But the great advances in recent times of medical knowledge, whether directly won or derived from kindred sciences, have shown such promise of abundant help for all, rich and poor alike, that the gifts are now directed with a broader hope upon medicine itself. Such gifts, and they have followed one another in an astonishingly rich profusion since the beginning of this century, do not derive from a purely intellectual interest in science. Their aim is practical, for the welfare of humanity; they are guided by the sense that medicine itself, the instrument, must be sharpened with a keener power of penetration into the tangled problems of disease. Merely to multiply hospitals is not enough, for there is still substance to justify the indignant comment of Tristram Shandy's father on the physicians' motto, *Ars longa, vita brevis,* "Life is short, and the art of healing tedious; and who are we to thank for the one and the other but the ignorance of quacks themselves—and the stage loads of chymical nostrums, and peripatetic lumber, with which in all ages they have at first flattered the world, and at last deceived it".

The practical art itself can make little true progress unless medicine is brought closer and still closer to the discipline of scientific thought. But the word 'science' in itself carries no reference to laboratories and their modern uses. It simply connotes exactness of knowledge. Plato in his Republic defined 'opinion' as a faculty wandering between ignorance and knowledge, and too often resting near the former state. It is not the traditional reliance on doctor's opinion, but proof of every clinical rule and determination of the laws co-ordinating the phenomena of disease that are needed if the subject is to take rank as a science.

There are faint-hearted people within medicine who feel that the complications of each individual patient and his disease are so manifold that the clear generalizations of an exact science can never be applicable in practice, and that the latter must always remain at the level of an individual art. Others who are outside of the clinical group believe that discoveries of far-reaching value, the issue of a science that is creative as well as exact, will so rarely have their parentage among clinicians that it is fruitless to attempt to foster their birth in other homes than those of the ancillary sciences, such as physiology, biochemistry, and bacteriology. If both these views were true, clinical medicine might remain a useful art but it could never gain the exactitude and fruitfulness of a science Good judges have decided otherwise, and laid plans for the embodiment of their views. To the practical English mind it is important to note the origin of these plans and their subsequent vigorous growth.

In 1913 the Royal Commission on University Education in London published its final report. Lord Haldane was chairman, and associated with him were Lord Milner, Sir Robert Morant and others, none of whom held medical qualifications. The great fracture of the War has broken the continuity of memory in many affairs, and it often escapes notice that many of the recent developments in London were foreshadowed in and owed their origin to the arguments of that report. In dealing with the teaching of medicine, Lord Haldane and his colleagues concluded that clinical medicine is capable of being treated scientifically, and that for this purpose the subject should be dealt with by men of the kind spoken of as university professors, who would do for medicine what other men do for physiology or chemistry. In order to enable each of such clinical professors to develop his subject by both teaching and research, it was proposed to equip him with a 'hospital unit' or service of beds, laboratories and assistants, all under his general control.

Soon after the War, in 1919, Sir George Newman announced a grant from the Board of Education for the immediate establishment of a number of such clinical units in certain medical schools of London, and their directors were afterwards given the status and responsibilities of professors in the University. The primary conception owed much to the examples already given by Germany and the United States, and at the outset it was nourished by great gifts from the Rockefeller Board. But time has proved its strength; and the Regius professorships of medicine in Great Britain, which are among the oldest established of all our university chairs, are now being one by one transformed into posts held by men who do not aim at individual reputation in practice but seek to establish their subjects on a broader basis as an exact science. Lord Nuffield's gift of £2,000,000 to the University of Oxford for a school of advanced teaching and research in the clinical subjects emphasizes both the momentum of this change and the hopes that ride by its side.

Exactness in medicine as a science, whether curative or preventive, has all too short a range of ascertained knowledge. The vastness of the unmapped stretches, where disease must be met and somehow or other dealt with as it arises day by day, makes the science seem so small and the art of medicine almost the only means for ready action. Who can best be entrusted with the duty of riding out to extend the borders of the known ? Physiologists and biochemists have claimed the honour, justly pointing to the work they have already done. But to Lord Nuffield and his advisers it seemed right to choose men who belong to a different group, clinicians, and his choice lacks neither precedent nor good argument.

In the same year as that in which the Royal Commission outlined its plan for medical education in Great Britain, research in medicine was suddenly given State recognition and endowment on a great scale by those decisions of Government which created what is now known as the Medical Research Council. Though always devoting the greater part of its resources to laboratory work by bacteriologists, chemists and others not in direct contact with the sick, the Council from the outset resolved to foster research by actual clinicians. It was happy in its first choice of a man to be given full opportunities for such work. Sir Thomas Lewis, with his beds, laboratories, and assistants at University College Hospital, London, has given knowledge of the highest value to medicine by his studies of diseases of the heart and blood vessels. So emphatic a success justified the Council in developing similar posts for clinical research in other medical schools ; and with the assurance of such possibilities for work in front of them, even before the advent of Lord Nuffield's endowments for clinical research, some of the ablest of the younger men in hospitals have chosen for their life's work research in that particular field which Sir Thomas Lewis by his recent writings and addresses has sought particularly to identify under the name of clinical science.

Neither the name nor the idea is new. But the steady advocacy and the proof of its importance have created a group of workers who will make of it almost a new science in Britain. Including as it does all exact knowledge concerning human disease, it is in that respect nothing more than the science of medicine, to which so many workers in the past have added from their various points of view. The fresh impress is in the emphasis on the possibility, and the need, of developing a science directly related to medicine and dealing with the clinical phenomena of disease.

The accepted medical sciences, as distinct from clinical science, comprise all those biological studies which contribute to the understanding of disease and which were originally developed by medical men because they felt the need for such ancillary knowledge. Physiology, bacteriology and the rest have shown such vigorous growth that each now prospers with the independence of a pure science. The separation was inevitable ; but thereby clinical medicine lost much of its own repute for scientific work, while the ancillary sciences acquired the term of being 'fundamental' because they revealed the main facts and laws of the working of the healthy body through which the disturbances wrought by disease might be analysed. For argument, let it be granted that in the future the deepest discoveries of far-reaching importance will be made by research in these separate studies. Such discoveries cannot be used at once in practical medicine. Some intermediate group of workers, equally trained in exact scientific judgment, must test and prove the way in which they may be applied to the management of human disease. The physiologist has learned that what is true for the frog may be untrue for the cat ; and even what is true in healthy man may not be true in disease. If life must be measured in terms of life, then medicine must be measured in terms of medicine. That is the responsibility of clinical science.

The British school of physiology has a world-wide eminence. Its great discoveries regarding the nervous control of the viscera and blood vessels were among its earliest achievements, and little has been added to the details of that analysis in the last thirty years. Time moved on, and still almost nothing was gained from that great store of knowledge until at last clinicians themselves began to test by experiment its applicability to diseased states in man. In this direction clinical science is complementary to the fundamental sciences, and as essential as they are for the progress of practical medicine. But the clinician is the first to be aware of the insistence of a medical problem and to define it : in the end, only he can test the accuracy of the proposed solution. The needed discovery will often be his own, but if it chances to be made by a laboratory worker in other biological sciences, it is plainly to the advantage of the latter in so far as public support of their sciences is concerned that the applicability of such discovery to practical medicine should be proved with the least possible delay. Indeed, those aspects of pure physiology and pathology which require experiments on animals would not be accepted as justifiable if they did not yield knowledge that finally gives help to both man and the animals.

There should, therefore, be no jealousy between clinical science and the sister subjects. Each relies on the other where medicine is concerned. For the fundamental sciences there may be fears that such great gifts as those of Lord Nuffield, opening too wide an irrigation channel over the new fields, may compromise their hopes of support. But the clinical work must be done, and the study of medical patients is costlier in all forms of maintenance than that of any other laboratory work. It cannot be stinted. For clinical science in its newer aspect there is a human need of intellectual sympathy and encouragement. Its work and its own proper discoveries tend to be disregarded in the domains of pure science, unless they happen to contribute facts or laws that are seen to be important also in those fields of work. The science must therefore stand in its own ground if it is to gain adherents and fulfil the responsibilities which are proper to it.

Some events in the history of medical progress more than a hundred years ago may be looked at in this reference. Thomas Young, whose intellect devised a theory of light and colours and went far in deciphering Egyptian hieroglyphics, was a physician. After years of study he wrote a book on consumption of the lungs, and to that subject even his great scientific powers could contribute nothing beyond a device for identifying pus cells in sputum by the coloured rings produced by the uniformly sized globules when the sputum was squeezed into a thin layer between two glass plates. Three years later, Laennec in Paris published his epoch-making observations on the use of the stethoscope and of physical signs for exact analysis, as proved by subsequent necropsy, of diseased states of the lungs. These discoveries were missed even by the inquiring genius of Thomas Young, and yet they were so great as to make all his treatise idle reading. Though demonstrably true, they are barely noticed in the history of scientific thought because they belong only to clinical medicine. They derived nothing from and contributed nothing to other sciences; but they had the exactness of proved knowledge and in that sense became a part of medical science.

Much of the best in medicine is knowledge of this type, gained by direct observation of the phenomena of sickness; but being self-contained and not linked by any clear laws with the generalizations of other sciences, it tends to be judged as falling below that which would entitle it to the rank of a science and being little more than the furnishing of a practical art. The exclusiveness of such a judgment might well be challenged. On the other hand, Young's observation on the sputum, though it added nothing to medical knowledge and only introduced an ingenious device, would by modern custom probably be spoken of as scientific because it was derived from the established body of mathematical and physical knowledge. The present fashion is to assume that there is nothing scientific in medicine unless it has been either derived from or re-affirmed by experimental tests in laboratories of the fundamental sciences.

Certainly in the past, medicine has taken a first but only half-hold of many discoveries, and then let them slip unproved out of her grasp because she lacked the technique of experiment and proof that has been the foundation of the biological sciences. The control of rickets and the whole range of modern progress in nutrition have thus tended to pass to the credit of physiology. But physiologists have their own problems to solve, and it is essential to the advance of a pure science that its quests should not be limited by the narrow horizon of what is visibly capable of practical use. There will be a long and wasteful delay in the progress of both the science and art of medicine unless the means are strengthened for prompt study of clinical questions by every available form of science, and equally for the testing and transference into clinical knowledge of any hopeful new discovery in physiology or the other sciences. Every part of such work will be scientific, while its direct concern with the questions of human disease is stated in its name of clinical science.

Engineering and metallurgy derive the whole of their scientific thought from the fundamental studies of physics, chemistry and mathematics. Geology derives still more widely. Yet in these subjects an independent science exists, and is creative in its own field. Clinical science in England at the moment makes use largely of the physiological approach to medical problems. With such methods clinical workers have made advances that are momentous in their own science, though some of them are of little import to physiology. The analysis of the different forms of irregularity of the heart-beat, their relationship to failure of the heart, and the appropriate therapy by digitalis provide one such instance. The delightful success of American work on the treatment of pernicious anæmia is almost entirely due to clinical research, while it has given to physiology new knowledge about the ripening of red blood cells that includes a process of such fantastic strangeness that no sane physiologist would have allowed himself even so much as to dream of its possibility. Each science learns from and helps the other.

Physiologists have taught all the 40,000 medical men in Great Britain. These practitioners of medicine are busy with their own technical art, and that is neither physiology nor clinical science, though it is inspired by each. Year by year their work grows more effective, thanks to progress in scientific knowledge of disease. Lord Nuffield's gift will augment the number of those aiding this advance by work in clinical science, and still leave them few in comparison with those in the other medical sciences whose work is less directly related, and therefore less immediately applicable, to the treatment and prevention of disease.

Chemical Exploration of the Stratosphere*

By Prof. F. A. Paneth

STUDENTS of the history of astronomy may remember that those of the natural philosophers in old Greece who favoured a geocentric conception pictured the universe as being built up of several spheres surrounding the earth. According to Aristotle, the sub-lunar world consisted of the four elements, each tending to its "natural place"; innermost was the core of the earth, surrounded by layers, first of water, then of air, and fire, wherever found, trying to rise to the top layer. Next came the realm of the "quinta essentia", the substance of the celestial bodies; but these were not supposed to circle in one and the same sphere. In order to explain the movements of the planets, Aristotle saw himself compelled to assume not less than fifty-six spheres in the sky, all concentric with the earth.

It looks somewhat like a revival of these old ideas that to-day science speaks of many concentric layers in the earth, sea and atmosphere. Since the development of modern seismology and geochemistry, it is known that the earth consists of at least four regions: a core of liquid iron in the centre, then a medium shell of, probably, sulphidic ores, covered by two outer shells of rocks of different densities. Fairly recently, in the early part of this century, it was discovered by Teisserenc de Bort that the thermal qualities of the atmosphere show a break when the height of about 11 km. (in our latitudes) is attained. In the lower part, called the 'troposphere', the temperature decreases regularly with increasing altitude until, at the height mentioned, about − 53° C. is reached. From here onwards, however, the temperature remains nearly constant at any height accessible to direct meteorological measurements. We have obviously entered a layer of the atmosphere in which different physical conditions prevail: the 'stratosphere'.

For a while it was assumed that the constant temperature of the stratosphere might extend to the top of the atmosphere. But from 1922 onwards it became clear that the structure of the atmosphere is much more complicated. We now know from indirect evidence, interpreted by Lindemann, Dobson and Whipple, that in regions at present beyond the reach of any thermometer, between 30 km. and 40 km., the temperature of the atmosphere begins markedly to increase again, and that this warmer layer is responsible for the reflection of sound waves; that at about 100 km. and again at 300 km. there exist strata of ionized air which play a role in the reflection of radio waves (Kennelly-Heaviside and Appleton layers); and that in the highest parts of the atmosphere a gaseous mass of about 1,000° C. is to be assumed. However complicated this may sound (even if we add that oceanographers nowadays distinguish between a 'troposphere', the upper layer of the sea in which the temperature decreases with descent, and a 'stratosphere' of fairly constant temperature below) we may still console ourselves by the thought that the modern scientific picture of the onion-like structure of the earth, sea and air is yet much less involved than the speculation of the ancient philosophers, and that its exploration advances quickly, thanks to the co-operation of various sciences.

While the temperature and the electrical state of the stratosphere have been the subject of many investigations, its chemical composition has seldom been studied. But so early as 1912, Tetens pointed out that a chemical investigation of the composition of the stratosphere would be the best, if not the only, means of deciding the question raised right at the beginning by the discovery of the stratosphere: Does the constancy of temperature mean that there is no convective motion of air-masses; does it prove the absence of winds?

It is not difficult to see why the chemist should be able to settle this question. If it were possible in a long vertical tube containing a homogeneous mixture of two gases of different densities to prevent every disturbance from outside, then we should expect the relative proportion of the gases no longer to remain constant throughout the length of the tube, but the heavier gas to concentrate near the bottom, the lighter near the top. This is a consequence of Dalton's law, which states that the variation with height of the density of each gas is the same as if it alone were present. The conclusion has never been experimentally verified, as it is scarcely possible to keep vertical gas columns of sufficient lengths—100 m. would be a good start—free from all disturbances. Only as a historical curiosity it may be mentioned that in the classical book on acoustics by Chladni (1802), an experiment is quoted by a Vienna professor who succeeded in separating the nitrogen and oxygen of atmospheric air in a vertical tube of not more than five feet length, simply by leaving it alone for one year!

---

* From the Friday Evening Discourse at the Royal Institution delivered on November 6.

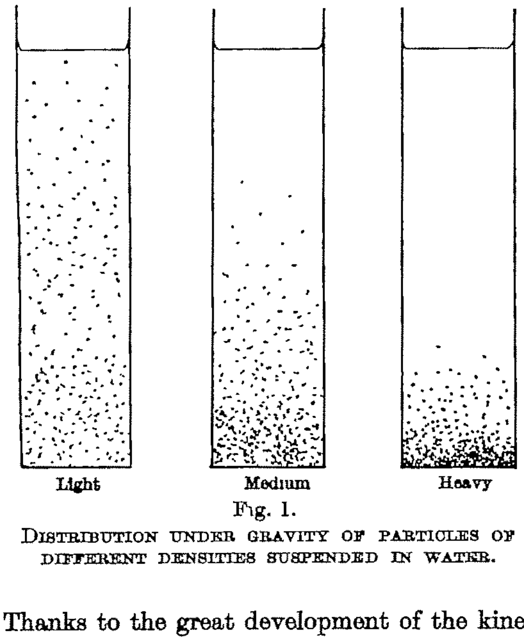

Fig. 1.

DISTRIBUTION UNDER GRAVITY OF PARTICLES OF DIFFERENT DENSITIES SUSPENDED IN WATER.

Thanks to the great development of the kinetic theory of gases we can, however, predict in every detail what is bound to happen in long vertical columns; and on a reduced scale it is possible to test the conclusions in a model experiment. Einstein was the first to point out that little particles suspended in water are subject to the same two conflicting tendencies as the molecules of a gas; on one hand they try to settle down, due to the force of gravity; on the other, their tendency to diffuse drives them asunder in all directions, including the one opposed to gravitation. As a result their equilibrium distribution must follow the same well-known 'barometric altimetry formula' for the decrease of concentration with height as does atmospheric air; with the one difference that, owing to the enormous contrast between the weight of visible particles and that of gas molecules, the phenomenon of thinning out with height must become perceptible at much smaller distances. The density of oxygen, for example, decreases to half its original value if we ascend to a height of about 5,000 m.; in a suspension of microscopic particles in water, the concentration should fall to half the initial value within a minute fraction of a millimetre, the rate of decrease depending, amongst other factors, on the specific weight of the particles.

Einstein's predictions have been tested experimentally by the French physicist Perrin and others. Fig. 1 illustrates on an enlarged scale what has actually been seen under the microscope. Each of the three suspensions, of heavy, medium and light particles, shows the regular decrease of concentration with height, following the barometric formula; but the one with the heaviest particles displays the phenomenon within the shortest range. If we mix the three emulsions by stirring, the particles will at first be homogeneously distributed throughout the whole column of water; but as soon as we leave them undisturbed—that means subjected no longer to large-scale mixing, but only to the forces of diffusion and gravitation—the height distribution peculiar to each of them will be restored, and so the percentage concentration of the heavier particles will increase near the bottom, of the lighter particles near the top.

Let us apply this knowledge to the atmosphere. It consists of a complicated mixture of gases.

TABLE 1.

COMPOSITION OF THE TROPOSPHERE (PER CENT BY VOLUME).

Nitrogen	78·08	99·99
Oxygen	20·95	
Argon	0·93	
Carbon dioxide . .	0·03	
Neon	$1{\cdot}8 \times 10^{-3}$	
Helium	5×10^{-4}	
Krypton . . .	1×10^{-4}	
Xenon .	1×10^{-5}	
Ozone	variable; $> 1 \times 10^{-6}$	
Radon (average near ground)	6×10^{-18}	
Hydrogen	doubtful; $< 1 \times 10^{-4}$	

In Table 1 the composition of atmospheric air is given. The content of water vapour, as is well known, is so variable that I have omitted it entirely; the table refers to dry air. The carbon dioxide, ozone and radon content, for different reasons, is also far from being constant. But the other gases are apparently present in the percentage given wherever in the whole troposphere a sample of atmospheric air may be collected. (Statements to the contrary in the older literature, by Wigand, Tetens and E. Erdmann and H. Lange, were based on very few inaccurate experiments and can be regarded as disproved; it is most unfortunate that they should still be quoted.*) This equal distribution is perfectly understandable as an effect of the frequent stirring of the troposphere by winds; but if it be true that in the stratosphere no mixing beyond the slow one due to diffusion takes place, we should expect to find there a partial separation of the gases according to their different densities. A careful chemical analysis of air samples taken at various heights in the stratosphere is, therefore, a means of testing the question of the stillness of the stratosphere air.

As to the chemical analysis of air, we may confine ourselves to the determination of a few representative constituents. By far the easiest measurement is that of oxygen, and this gas has, therefore, been chosen by most laboratories; its absorption can be effected by phosphorus, heated copper or pyrogallic acid, or it may be removed by catalytic combustion with hydrogen. Its density, however, is only slightly greater than that of air (see Table 2) and for this reason it is not nearly the best for the present purpose; but the determination of the heavier argon is not so simple, and that of the minute traces of the very heavy gases, krypton and xenon, quite impossible in small air samples. As a specimen of a gas lighter than air, helium is the most suitable, since the lightest known gas, hydrogen, is not present in any measurable quantity; for the determination of helium we have developed a micro-method which enabled us to measure quantities of a few millionths of a cubic centimetre with an accuracy of 1 per cent.

TABLE 2

DENSITIES OF THE ATMOSPHERIC GASES.

	Formula	Molecular weight (O = 16·000)	Density (Air = 1·000)
Helium	He	4 002	0·1381
Neon	Ne	20·183	0 6963
Nitrogen	N_2	28·016	0·9670
Oxygen	O_2	32 000	1·1053
Argon	A	39·944	1·377
Carbon dioxide	CO_2	44·00	1·529
Ozone	O_3	48 000	1 624
Krypton	Kr	83 7	2·868
Xenon	X	131 3	4·525

(To be continued.)

Obituary Notices

Dr. R. J. Tillyard, F.R.S.

THE death of Dr. R. J. Tillyard took place in Australia on January 13, as the result of a motor-car accident on the road between Canberra and Sydney. Since Tillyard was one of the best known entomologists of the present day, his decease will come as a shock to his colleagues in many parts of the world.

Born on January 31, 1881, Robin John Tillyard was the son of J. J. Tillyard, of Norwich. His education was at Dover College and Queens' College, Cambridge, where he gained a mathematical scholarship. He became senior optime in 1903 and graduated M.A. in 1907. Ill-health, especially rheumatism, led him to seek a livelihood abroad, and he went to Australia in 1904 as mathematics master at Sidney Grammar School. In 1909 he married Miss Patricia Craske, a daughter of Mr. W. R. Craske, J.P., of Borstal, Rochester.

On gaining a Government studentship at the University of Sydney, Tillyard relinquished the career of schoolmaster and in 1915 became Macleay fellow of the Linnean Society of New South Wales, an office which he held until 1920. A short period before the Great War he became involved in a railway accident which incapacitated him for a long time and permanently altered his bodily figure. During these years he had a young family to provide for on slender means. At this juncture, he owed much to his wife's skill and devotion in managing all family affairs over a difficult period. In spite of being still an invalid, he took a B.Sc. research degree at the University of Sydney and, some years later, became a D.Sc. In 1920 he was appointed chief of the Department of Biology at the Cawthron Institute, Nelson, New Zealand. Tillyard remained at Nelson until 1928, when he became Chief Commonwealth Entomologist for Australia—a new and highly paid post with more exacting duties. He held this post for six years but, owing to health reasons, he had to retire, the Federal Government granting him a proportional pension.

Tillyard's early researches were concerned with dragonflies and, beginning from about 1905, he published a long series of papers on these insects, mostly in the *Proceedings of the Linnean Society of New South Wales*. His most important original study in this field is his paper "On the Rectal Breathing Apparatus of Anisopterid Larvæ" which was published by the Linnean Society of London (1916). It is a work of outstanding merit and secured for him the Crisp Medal and Award of that Society. About 1915 he became interested in the wonderful Neuroptera of Australia, publishing many papers on these insects. His work on the Chrysopidæ showed with remarkable clarity how the intricate venation of these creatures is prefigured by the tracheation. After publishing his well-known book "The Biology of Dragonflies" (1917), Tillyard completed a study of venation and its bearings on the phylogeny of the Holometabola. The outcome were his papers on the "Panorpoid Complex" wherein, by a closely reasoned analysis, he claimed that under this title were to be grouped all the higher orders other than the Coleoptera and Hymenoptera.

Tillyard's many contributions on fossil insects placed him as the foremost authority on the subject in his day. The rich beds of Upper Triassic and Lower Permian age in Australia, and of Lower Permian date of Kansas, provided him with a wealth of material. In a relatively short time, Tillyard did much towards changing our knowledge of Permian and Triassic insects from being the most fragmentary into becoming among the most complete of any geological period. He also made many remarkable accessions to our knowledge of the affinities of various orders in bringing to light generalized or annectant types. With so extensive an output of work to his credit, it is scarcely surprising that here and there his conclusions led him astray.

After resigning his last appointment, Tillyard regained much of his health, and one of his last efforts was a conjoint memoir with the late Sir W. T. E. David on Proterozoic fossils of the Adelaide Series (1936). Only three weeks ago a letter by him in NATURE (January 9) made known a Mecopteroid insect bearing upon the ancestry of Diptera.

As an applied entomologist, Tillyard's notable work was the successful introduction of the Chalcid, *Aphelinus mali*, into New Zealand. As an agent controlling the woolly aphis of the apple, it greatly benefited growers by minimizing the necessity for insecticides. Tillyard was a whole-hearted believer in biological control, and initiated schemes for the repression of noxious plants, by introduced phytophagous insects, for both New Zealand and Australia. The results, however, have not, so far, borne out his earlier expectations.

Tillyard's predominant interest was in insect phylogeny and, in this connexion, he published papers on almost all the lower orders and especially on the more primitive forms. Altogether, he must have published about two hundred papers. The great part of this work is of high quality and will aid and stimulate those who come after him. He also found time to write a large text-book on the "Insects of Australia and New Zealand" (1926), profusely illustrated from drawings made by his wife.

For a number of years past Tillyard was keenly interested in psychical phenomena. At one time, these matters absorbed his attention to an extent which perplexed some who knew him. He believed in the necessity for proper scientific analysis of such manifestations and took every opportunity of gaining first-hand experience.

At the time of his death, Tillyard was an honorary fellow of Queens' College, Cambridge: he graduated Sc.D. (Cantab.) in 1920 and became F.R.S. in 1925. He is survived by his wife and four daughters.

A. D. IMMS.

Sir David Semple

WE regret to record the death, which occurred on January 7 at the age of eighty years, of Sir David Semple. Sir David graduated with honours at Queen's University, Belfast, and also took a diploma in public health before entering the Army Medical Corps, as it then was, as early as 1883. After service in India and elsewhere, he became associated with Almroth Wright as assistant professor of pathology at the Army Medical School at Netley from 1904 until 1909, and the good work he then did in bacteriological research opened up a varied and valuable career. Much of his earlier work was in connexion with anti-typhoid inoculation and other immunological researches, and this led to his appointment as a member of the committee for investigation of enteric fever in India from 1905 until 1909; this committee did important work which led to enteric being dethroned from its unenviable position of constituting by far the most important cause of sickness and mortality in the British Army in India.

In 1905 the first Pasteur Institute of India was founded at Kasauli in the Himalayas, not far from Simla, under a committee which had been largely instrumental in raising funds for its establishment, and David Semple's reputation already stood so high that he was selected as the first director during the early critical years, 1900–5. Here he did what was probably his most important work in introducing the use of carbolized hydrophobia-infected rabbits nervous system in graduated doses; for this has enabled the vaccine to be preserved and sent for use to hospitals and dispensaries all over India, with the great advantages of enabling the treatment to be carried out without the delay and expense of sending the patients many hundreds of miles to a central Pasteur Institute.

In 1905 Semple was called upon to occupy the more important post of director of the newly established Central Research Institute of India, also at Kasauli, which was now organized as the headquarters of the newly established Bacteriological Department of the Government of India for general medical research purposes. He had now completed more than twenty years service in the Royal Army Medical Corps, as it had now become, so he retired from that service with a pension, and served in his new post until 1913. During a portion of that time he was a member of the Central Malarial Committee and of the Scientific Advisory Committee for Medical Research under the Government of India. His work was now mainly of an administrative nature, and he did much to help and encourage younger research workers attached to the Research Institute. On retiring from service in India under the age rules in 1913, he was fortunate enough to find fresh administrative employment in Egypt as Director-General of the Public Health Department from 1913 until 1918, when he eventually returned to England to a well-earned rest.

Semple was of a retiring disposition, but a sound patient worker, and it was only those who had the privilege of his friendship who fully appreciated his worth.

Prof. K. K. Mathur

PROF. KRISHNA KUMAR MATHUR's premature death on July 18, 1936, at the age of forty-three years, has deprived India of an eminent geologist and educationist. After finishing his secondary education, Mathur joined Agra College, where he came in close contact with the inspiring personality of Prof. N. C. Nag. Later he continued his studies at the Imperial College of Science and Technology, where he took the associateship of the Royal School of Mines in mining and mining geology, and the B.Sc. degree in mining, with first-class honours, of the University of London. There, too, he stood first among the successful candidates of his group and was awarded the De la Beche Medal.

Soon after his return to India, Prof. Mathur's services were secured by the Benares Hindu University as the University professor of geology in the year 1921. There he soon established himself as a great teacher and administrator. The Department of Geology owes its growth and development to Prof. Mathur, who was its head from the very beginning. His personality attracted students from all parts of India. At Benares he built up a school of geology, which is all-India in its character. His indomitable spirit in the face of hardship and his great love for the science of geology were a source of great inspiration to his students, who are spread far and wide in India, some of them holding important offices. His colleagues in the University held him in the highest esteem, and when he was appointed principal of the College of Science, constituted in 1935, everyone was indeed very happy at the selection.

In the field of research Mathur's principal contributions comprise the petrology of the Deccan Trap igneous activity. He carried out investigations of the various differentiates and threw much light on the genetic processes leading to the formation of the different types. His presidential address to the Geology Section of the Bombay meeting of the Indian Science Congress in 1934 on this subject will continue to be a valuable work of reference for a long time to come. His research activities also extended to stratigraphy, mineralogy and colloidal chemistry.

Amongst the scientific workers in India, Mathur held a prominent position. He was vice-president of the Geological, Mining and Metallurgical Society of India for two sessions. He was a foundation fellow of the United Provinces Academy of Sciences (now the National Academy of Sciences), the Indian Academy of Sciences, and of the National Institute of Sciences in India.

On the personal side, Prof. Mathur was a man of strong principles and high ideals. As an administrator, his sense of justice was great, which won for him love from all quarters. He was strict in imposing rules but very liberal in judging faults. He was simple, sincere and a great philanthropist. His purse was always open for the poor student and for the cause of science. He carried his greatness with charming modesty; he was a selfless and conscientious worker.

Prof. D. F. Fraser-Harris

PROF. DAVID FRASER FRASER-HARRIS, whose death occurred on January 3, was born on February 24, 1867, the eldest son of Mr. David Harris, of Bath. He studied medicine at the University of Glasgow, where he obtained the Neill Arnott Prize in physiological physics in 1890 and the British Medical Association Prize on the effects of alcohol in 1892. He qualified in 1893 and for the next five years was senior assistant to the professor of physiology and Muirhead demonstrator in physiology at Glasgow. He then went to St. Andrews as acting professor of physiology until 1908. He also lectured on physiology and hygiene at Manchester and Birmingham, where he obtained the degree of doctor of science and was made a member of a committee to investigate artificial respiration apparatus.

Prof. Fraser-Harris was an original member of the Biochemical Society and president of the Scottish Microscopical Society in 1908–9. In 1911 he was appointed professor at Dalhousie University, Halifax, Nova Scotia, which he represented on the Medical Council of Canada, and he remained there until 1924, when a breakdown in health compelled him to resign his appointment.

Prof. Fraser-Harris was a lucid and prolific writer on the physiology of the nervous system and the history of medicine. In addition to being general editor of the Modern Health Series, to which he contributed "Nerves—Master System of the Body" (1927), he was author of "The Functional Inertia of Living Matter: a Contribution to the Physiological Theory of Life" (1908), "Coloured Thinking" (1928) and "Morpheus or the Future of Sleep" (1928). As member of the editorial board of *Medical Life*, the official organ of the American Society of Medical History, he contributed a number of interesting essays to that journal on eminent undergraduate observers, medical presidents of the Royal Society, Shakespeare's perception of the functional importance of the brain and other medico-literary topics. His interest in other branches of medicine is shown by his publication last year of a little work entitled "Aural Therapy in Relation to Deafness" and an article in the *Medical Press and Circular* of October 28 on "The Duke-Fingard Method as applied to the Respiratory System". He is survived by his widow and a son, a sub-lieutenant in the Navy.

We regret to announce the following deaths:

Sir John A. F. Aspinall, past-president of the Institutions of Mechanical and Civil Engineers, and also of the Institution of Civil Engineers of Ireland, on January 19, aged eighty-five years.

Prof. David Ellis, professor of bacteriology and superintendent of the Schools of Pharmacy and Bakery in the Royal Technical College, Glasgow, on January 16, aged sixty-two years.

Dr. Marshall A. Howe, director of the New York Botanical Gardens, an authority on the seaweeds and liverworts of North America, on December 24, aged sixty-nine years.

News and Views

Genetic Theory and Practice in the U.S.S.R.

A REPORT of the fourth session of the Lenin Academy of Agricultural Sciences, which was held in Moscow in December last, has been received from the Soviet Union Year Book Press Service, 623–4 Grand Buildings, Trafalgar Square, London. Apart from seventy-one special papers, there was a general debate on the present position of research in genetics. This apparently took the form of an attack on modern genetic theory by experts who have been engaged in the study of practical problems unrelated to genetics. The grounds of the attack were ostensibly twofold. First, geneticists like Muller and Vavilov were said to have neglected the Marxian principle of the unity of theory and practice in failing to keep their work in touch with the needs of farmers. Secondly, the primary assumptions of genetics were held to be invalid. Presumably, in the absence of other evidence, the second contention was deduced from the first. The attack was reinforced by pointing to work like that of Michurin and Lysenko which, unhampered by academic prejudice, has yielded results of immense practical value by methods of trial and error.

MICHURIN is described as a "self-made practical plant breeder"; his published work has unfortunately not been translated into any foreign language. He is understood, however, to have made hybrids and discovered sports in various economic plants of a kind never produced elsewhere. Lysenko, on the other hand, is well known as the author of the technique of vernalization, which he invented apparently without knowledge of the previous experiments conducted abroad on the same subject. This worker went further than the other disputants and promised that the physiological behaviour acquired by plants under his treatment could be inherited, winter wheat being turned into spring wheat and *vice versa.* If this were true, the tedious methods of plant breeding now practised by orthodox geneticists in Prof. Vavilov's institutions would of course be superfluous.

THE situation revealed by this discussion is astonishing in more than one respect. It is a commonplace and as old as Aristotle for scientific men unfamiliar with experimental methods to set forth Lamarckian doctrines in explaining evolution. For experimental workers to set out a Lamarckian method for the advancement of practical breeding is, however, something new and particularly remarkable in the Soviet Union, where the moral bias of this ancient myth might well have made it suspect. Still more astonishing is it to find that these arguments are combined with a charge of doctrinal incompetence against Muller and Vavilov, who, while making fundamental contributions to genetic theory, have probably done more than any other living workers in this field to show its practical value to mankind.

Scientific Freedom

THE following resolution was adopted at a meeting held on December 31 by the American Society of Naturalists during the recent Atlantic City meetings of the American Association for the Advancement of Science: "The American Society of Naturalists observes with regret an increasing tendency in certain parts of the world to require of investigators the conformity of their research to officially prescribed doctrines. This society wishes to emphasize that intellectual progress is compatible only with perfect freedom in the conduct of investigation and in the announcement both of results and of conclusions based upon those results. Attention is called also to the fact that the scientific world can place no reliance upon reports of research carried on under conditions which limit its freedom by an enforced agreement with any preconceived views or dogmas."

American Flood Devastation

LESS than a year has elapsed since, on March 28, 1936, we recorded a serious flood visitation suffered on the west of the Atlantic, and now once more the peril of the waters is rife in many eastern States of North America. Due to extremely heavy rainfall, the Mississippi and Ohio Rivers have been steadily and rapidly rising, overflowing their banks and inundating the surrounding country. The whole of the Ohio valley is affected and it is estimated that, up to the time of writing, some 750,000 people have been rendered homeless in thirteen States, with every expectation of a greatly increased total. The deaths so far number more than a hundred and many people are missing. Pittsburgh (Pennsylvania) with a population of 700,000, and Cincinnati (Ohio) with a population of 450,000, are menaced with a repetition of the tragic experience last year when many of the inhabitants in the former town lost their lives. At Cincinnati, the river has risen to the abnormal height of more than 70 feet, the highest level recorded for almost fifty years. Wheeling, a busy industrial centre in West Virginia, is threatened with the complete submergence of the island on which part of the town is built.

PERHAPS the most exciting incident of the calamity has been the compulsory opening at Portsmouth (Ohio) of the main sewer sluices to relieve the heavy pressure of water against the river embankments, which it was feared were on the point of collapse. After dramatic warning by factory sirens and locomotive whistles to enable the residents to evacuate houses and buildings and find refuge on higher ground, water from the river was allowed to flow into the business quarter of the city to a depth in places of 10 ft. At Cincinnati, the situation was further imperilled by the escape of oil from the Standard Oil Company's storage tanks, which caught fire and transformed the river surface into a sheet of flame, extending for a distance of four miles and doing damage estimated at about £200,000. Fire broke out, too, at Louisville (Kentucky) where martial law had to be proclaimed, as also at Columbus (Ohio). The sufferings of the homeless are increased by inclement weather conditions, with intense cold, snow and sleet. President Roosevelt has issued a proclamation stating that it is imperative to raise a fund of at least £400,000 to relieve the destitution of the victims.

Flooding in Southern England

THE catastrophic experience in the United States is reflected in a minor degree in the southern counties of England, where persistent rains have caused inundations in Kent, Sussex, Berkshire, Wiltshire, Northamptonshire, Bedfordshire and elsewhere. The valley of the Thames in many places is under water and the river is running more than 'bank high', the rate of flow having reached 8,700 million gallons per 24 hour day, as compared with the 9,000 million gallons recorded on January 3 last year, during a period of exceptionally heavy rainfall. The standard daily average for the month of January is 2,407 million gallons. Although the latest indications are that the peak level has been passed, yet, with an outlook presaging more rain in all districts, the prospects of an early subsidence of the flood waters are by no means reassuring, and much discomfort to marooned residents and interference with road traffic is being experienced.

Leopold von Schrötter (1837-1908)

A COMMITTEE of prominent Viennese physicians and laryngologists has recently been formed to commemorate the centenary of the birth of the man, equally illustrious as laryngologist and physician, whose full name and titles were Hofrat Prof. Dr. Leopold Ritter Schrötter von Kristelli. He was born at Graz on February 5, 1837, the son of the eminent chemist who discovered amorphous phosphorus. He studied medicine at Vienna, where he qualified in 1861. From an early stage in his career he took a keen interest not only in diseases of the chest, which he had an unrivalled opportunity of studying under Prof. Skoda, the great authority on this subject, but also in laryngoscopy, the importance of which to the physician he was the first to emphasize. During his subsequent career he occupied the important positions of director of the first laryngological clinic to be established and later the chair of clinical medicine in the University of Vienna. His principal work was a book on diseases of the larynx, trachea, nose and throat, which for a long time was the standard publication on this subject. He also contributed important articles to various systems of medicine on diseases of the heart and pericardium and syphilis of the larynx. Lastly, he deserves recognition as being one of the first to introduce sanatoria for the treatment of pulmonary tuberculosis, and to combat the pessimistic outlook of the medical profession regarding the cure of this disease. His death took place on April 22, 1908.

Severance of Britain and the Continent

IN another column of this issue of NATURE (see p. 200) there appears a brief account of an archæological investigation of the submerged land-surface of the Essex coast by a sub-committee of the Fenland Research Committee. Questions of land elevation and submergence are naturally of much interest to prehistorians, more especially in relation to questions of dating, as well as of the possibilities and means of contact and communication between early cultures and peoples. One of the most important of such inquiries is that of the period at which separation of Britain from the Continent took place. In the same issue of the *Proceedings of the Prehistoric Society* in which the report on the submerged area of the Essex coast appears, Mr. Philip Ullyott, of the Department of Zoology, Cambridge, opens up a new line of evidence for dating this severance in "A Note on the Zoogeographical History of North-western Europe". In this he examines the geographical distribution of certain types of flat-worms (planarians) belonging to the same group and living in fresh-water, but adapted to different temperature ranges. His conclusion, in brief, is that the distribution of these types suggests that Britain must have separated from the Continent after the average summer temperature had exceeded 12° C., but before it had reached more than 16° C.

THANKS to the studies of Scandinavian workers, the curve of mean summer temperature during post-glacial time is known fairly accurately. It is, therefore, possible to say that the breaking of the land surface, across which the flat-worms migrated in fresh-water from the Continent to Britain, must have occurred during the Boreal period, but before its later stage, when the temperature curve rose to its maximum during post-glacial time. This conclusion agrees remarkably closely with the evidence of palæobotanical investigation, which points to an early Boreal phase, c. 6800–5000 B.C. As is pointed out in an editorial note, there is archæological support for this dating in the close connexion of the Baltic and Britain in the Continental period, while certain types become infrequent in Britain in the late Boreal period, and by Atlantic times the forest culture of south-east Britain had become quite distinct from the Ertebölle of Denmark and Schleswig-Holstein.

Snow

IN his Friday evening discourse at the Royal Institution on January 22, Mr. Gerald Seligman discussed "The Nature of Snow". He commenced by showing how the molecular structure of ice accounts for the hexagonal structure of ice crystals. He reproduced Tyndall's experiment of forming 'negative crystals' in ice by passing a beam of light through it. A cinematographic reproduction of the same experiment showed the formation of these 'crystals' under high magnification. Ice evaporation is stimulated by a comparatively high temperature, and the reverse process—reconsolidation—by a low temperature. Mr. Seligman stressed the importance of sublimation in every question affecting snow and snowcraft. The life-histories of different types of snowflakes under varying atmospheric conditions were then dealt with. Passing now to *firnification*, or the changes of the snowflake after lying on the ground, Mr. Seligman showed the complete cycle from newly-fallen snow to advanced firn snow by photomicrographs taken by him in the Alps and by scenic views illustrating the different kinds of snow surfaces encountered by the mountaineer or explorer. The process is essentially one of a consolidation of the fine, newly-fallen snow, occasionally containing as much as 89/90 of air, to one of pure ice containing little or no air at all. The final stage of firnification, the genesis of glacier ice, has never been fully recorded, and this is to form the subject of a research now in course of preparation by the lecturer who showed tools for the purpose lying on the table. Dealing briefly with new snow avalanches, Mr. Seligman used some of his microphotographs of firnification to show why snow slopes do not as a rule become dangerous until the temperature has risen after a snowfall—a practical point of value to the ski-runner. Turning next to the effects of wind upon snow, Mr. Seligman showed photographs of a number of wind-formations, including sastrugi, cornices, and snow 'wind-packed' or hardened by a wet wind. Wind-packed snow causes wind-slab avalanches, which consist of hard brittle drifts of snow lying loosely on steep slopes. These, if disturbed, break into blocks and form dangerous avalanches. A knowledge of the weather conditions which cause this type of avalanche has already proved of value to Everest climbers.

Harry Price Library of Magical Literature

To celebrate the transference of the library and records of the University of London Council for Psychical Investigation to the new University building in Bloomsbury, a dinner was held on January 22 at the Hotel Splendide. The occasion was also a mark of the Council's appreciation of the valuable work which Mr. Harry Price has done for psychical research and of his generosity to the University, and an illuminated testimonial to that effect was presented to him. The chairman, Dr. C. E. M. Joad, in complimenting Mr. Price, pointed out that in the early stages of all sciences, the experiments were carried out by private individuals at their own expense, and that it was to co-ordinate such activities and avoid acrimonious correspondence and personal animosities, that the Royal Society itself was founded. Mr. Price, in his reply, gave a short survey of the positive results of his many years of investigation, and concluded that sufficient evidence has been obtained to justify scientific investigation of telekinesis, thermal variations, teleplasmic masses, secondary trance personalities and extra-sensory perception of various kinds. The future of psychical research, he said, lies with the universities, and already there are six universities abroad taking the study seriously. The evening concluded with a demonstration by Mr. and Miss Tree, the foremost vaudeville telepathists in Britain. Their performance is remarkable for the extraordinary rapidity with which their code-system can be worked.

The Society of Smeatonian Civil Engineers

AMONG the least known engineering societies is that of the Smeatonian Society of Civil Engineers, which to-day exists mainly for social intercourse and has a small but select membership. When it was founded in 1771 it had as its aim the furtherance of professional knowledge. Its history has never been written fully, but on January 20, at a meeting of the Newcomen Society held at the Institution of Civil Engineers, Mr. S. B. Donkin gave an interesting account of its early fortunes. From the technical point of view, the most lasting result of the Society was the publication in 1812 of the four volumes of the "Reports of the late John Smeaton". In the preface to this and in two minute books are contained what is known of the Society in its early days. It was the increasing demands being made on canal, harbour and bridge builders which led to the formation of the Society, it being felt that good results would accrue from members of the civil engineering profession meeting together to discuss their various projects. That they did so in a friendly manner can be seen from the minute of a meeting in 1778 which "was spent canallically, hydraulically, mathematically, philosophically, mechanically, naturally and socially". The original society founded in 1771 came to an end in May 1792, but was almost immediately revived when, as the minute records, "The first meeting of this new institution The Society of Civil Engineers was held on the 15th of April 1793 by Mr. Jessop, Mr. Mylne, Mr. Rennie and Mr. Whitworth". Smeaton had been a leading figure of the old Society but he had died in October 1792. Soon after the revival of the Society, it learnt that Sir Joseph Banks had purchased all Smeaton's manuscripts and drawings, and it was with his concurrence the Society undertook the publication of Smeaton's "Reports". At the dinners, later on, five toasts were instituted, one of which was to "The memory of our late worthy brothers—Mr. Smeaton, Mr. Mylne, Mr. Watt and Mr. Rennie", and these toasts are still the order of the day at dinners of the Society. The Society, it may be added, had little, if anything at all, to do with the formation of the Institution of Civil Engineers, which arose from the efforts of half a dozen young engineers with their fortunes still to make.

Recent Acquisitions at the Natural History Museum

THE human remains from the Pleistocene deposits of Kenya Colony, on which much of Dr. L. S. B. Leakey's work is based, have been presented to the Department of Geology by the president and council of the Royal Society, through Dr. Leakey. The Mineral Department has received from the proprietors of the Hup Tuck Kongsi mine in the State of Selangor, Federated Malay States, the gift of an unusually large mass of cassiterite, showing numerous well-developed crystals. Cassiterite, which is more popularly known as tinstone, is almost the only source of tin and is therefore a valuable ore. Very occasionally it has been found in large enough crystals for cutting as gem-stones. The crystals in the present mass are at the best translucent at the surface. In colour they are mainly reddish brown, but some are black. Dr. Germaine A. Joplin, of the University of Sydney, has given a series of igneous rocks described by her, and rocks described in the Records of the Geological Survey of New South Wales are a donation from the Curator of the Mining and Geological Museum, Sydney. Dr. K. S. Sandford has presented the series of rocks which he collected when with Major Bagnold's expedition in 1932 and has since described. An opaque crystal of scheelite from Perak, larger than any hitherto in the Museum, has been given by Mr. John Weekley. Of considerable historical interest is the diary kept by Robert Allan (1806–63) during a visit to the Mediterranean in 1830, which has been given by Miss B. M. Clay, one of his descendants. Robert Allan was the son of Thomas Allan (1777–1833), the Edinburgh banker, whose mineral collection was bought after his death by R. H. Greg and acquired by the British Museum in 1860. Many of the minerals and rocks collected during this expedition are in the Mineral Department.

THE Department of Botany has received 1,650 plants collected by Messrs. G. Sherriff and F. Ludlow in Bhutan and Tibet. The route followed was from the Assam plains near Gauhati, through eastern Bhutan. Tibet was entered up the Nyan Jang Chu, a river rising north of the main Himalayan range which cuts its way through the range and flows south to join the Manas River. The plateau region was crossed and one of the headwaters of the Subansiri River was followed down. There six months were spent with Tsari as a centre, an area which proved very rich in alpine flora, some of the grassy hill-sides, above the tree-line, being literally covered with Primulas. After the flowering season was over, seeds were collected. It is probable that several interesting horticultural plants will be introduced to British gardens, for a number of new species of *Primula* and a new *Mecanopsis* were found. The specimens are exceedingly well preserved and the collection is a most valuable addition to the series of Himalayan plants in the Department. Among purchases are 600 flowering plants from the west-central district, Sikang, of China, the first consignment of a set of Dr. Harry Smith's collections on his recent expedition; the herbarium of A. L. Hübl, containing 4,600 specimens chiefly from Austria, and the moss herbarium of the well-known Dutch bryologist Fr. Verdoorn, comprising about 3,200 specimens.

Alcohol and Motor Accidents

AT a meeting of the Society for the Study of Inebriety on January 12 reported in the *British Medical Journal* of January 23, Dr. H. M. Vernon stated that though the maximum of road traffic accidents during the last two years was a little less than in 1934, the fatalities still averaged 18 a day and the injuries more than 600. Half the deaths were among pedestrians and a fifth among pedal cyclists, while drivers of motor vehicles and their passengers had only a third to a fourth as many accidents as pedestrians. Although the data of the Ministry of Transport indicate that only 1 in 80 of the road fatalities are due to persons obviously under the influence of drink, the evidence from America suggests that alcohol plays a much larger part in motor accidents. Alcohol even in moderate quantities frequently affects driving capacity, and in particular causes drivers unconsciously to increase their speed, which is the most important factor in the causation of fatal accidents. Examination of the blood or urine by Widmark's method shows the following correspondence between the alcohol content and the clinical symptoms. In persons with 1 part of alcohol per 1000 in the blood, 40–60 per cent were found to be "under the influence"; of those with 1·7 parts, 80–88 per cent were so affected, and of those with 2 parts all were affected. Dr. Vernon has come to the conclusion that abstinence from alcohol should be practised for several hours before driving as well as during its course, as the rate of disappearance of alcohol from the blood is very slow.

Communal Aerials for Radio Reception

IN large towns and cities, the provision of a good aerial generally presents many difficulties, especially in houses divided up into self-contained flats. In the latter case, it would be necessary to erect on one roof a number of separate aerials which would satisfy the varying requirements of the listeners. In some places also there is an almost insuperable difficulty owing to interference from electric motors and other electric devices. Some years ago the Philips Research Laboratories at Eindhoven, Holland, evolved a communal aerial system which they call the 'Antennaphil' which surmounts most of the difficulties met with in practice. A description of it is given in the *Journal* of the Philips Research Laboratories of August last. In this system an aerial of suitable dimensions is erected at a spot where interference is limited, for example, at a height of twenty feet above the roof. Through a specially screened conductor made as short as possible, the aerial is connected to an aerial signal amplifier, from which the incoming signals are transmitted to a number of receiving sets through a lead-covered cable which acts as a screened distributing circuit. Up to fifty sets can be connected to an aerial fitted with this form of amplifier. If the distance of the spot from which reception, practically free from interference, can be received is a few hundred yards, then the number of sets is less. But even up to a distance of 1,000 yards, several sets can be supplied. An aerial of this type has been in use at the laboratory for several years at a distance of 200 yards, and has ensured reception free from all interference. It is proved that a concentric cable of suitable dimensions is the best to use for high-frequency distribution.

"For Intellectual Liberty"

THE Society "For Intellectual Liberty", which was founded early in 1936 as a rallying-point for intellectual workers concerned with the active defence of peace, liberty and culture in the present conditions of the world, has recently issued its first bulletin.

The Society was formed as a result of an appeal from the French Comité de Vigilance des Intellectuels Antifascistes, which in January called a conference where it was decided to form an International Federation of Intellectual Workers. The bulletin in question describes the growth and activities of the British group from its original membership of fifty. The group has worked in close touch with the National Council for Civil Liberties, from which it differs chiefly in its wider concern with domestic and foreign affairs, and with various committees for the assistance of victims of Fascism and latterly with organizations to provide help for the Spanish people. It is not a party political organization and its present supporters are drawn from all shades of political opinion. It is broadly democratic and international in outlook, and by arranging for discussions among its members seeks to find the greatest measure of agreement on such questions as the need for a Popular Front or of the best way of forming it; on the question of armaments, the League of Nations and collective security, and on the practicability of removing, by economic or political action, the causes of war. The Honorary Secretary is Margaret Gardiner, 23, Haymarket, London, S.W.1.

Birth- and Death-Rates for 1936 in England

ACCORDING to a return published by the Registrar-General, the birth-rate in England and Wales during the year 1936 is provisionally estimated at 14·8 live births per thousand of the population, and the crude death-rate at 12·1 deaths per thousand of the population. The number of deaths of children under one year, per 1,000 live births, was 59. The birth-rate for 1936 is 0·1 above that for 1935, and 0·4 above that of 1933, the lowest on record. The crude death-rate is 0·4 above that of 1935 and 0·7 above that of 1930, the lowest on record. The infant mortality is 2 above that of 1935, which was the lowest on record, and is the same as that of 1934, the previous lowest on record. In 122 county boroughs and great towns of England and Wales, including London, the birth-rate during 1936 is provisionally estimated at 14·9 live births per thousand of the population, the crude death-rate at 12·3 deaths per thousand, and the deaths of children under one year at 63 per 1,000 registered live births. The corresponding figures for the 143 smaller towns with estimated resident populations of from 25,000 to 50,000 at the 1931 census are estimated as follows: birth-rate, 15·3, crude death-rate 11·7 and infant mortality 55. In the Administrative County of London the corresponding figures are estimated at: birth-rate, 13·7, crude death-rate, 12·5, infant mortality, 66. These figures are provisional, and may be subject to readjustment before the publication of the Registrar-General's Statistical Review in July.

Sir George Beilby Memorial Awards

THE administrators of the Beilby Memorial Fund, consisting of the presidents, treasurers and secretaries of the Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals respectively, have announced awards of a hundred guineas each to Dr. B. S. Evans and Dr. W. H. J. Vernon. Since 1919, Dr. Evans has been attached to the Research Department of Woolwich Arsenal, where he now holds the position of a scientific officer. He has devised numerous analytical methods for the separation and determination of metals, and contributed the chapters dealing with the methods of analysis applicable to lead, bismuth, arsenic, antimony, tin, iron, chromium and metallic constituents of steel in Mitchell's "Recent Advances in Analytical Chemistry". Dr. Vernon was appointed investigator to the newly-formed Atmospheric Corrosion Committee of the British Non-ferrous Metals Research Association in 1921. His experimental work was carried out at the Royal School of Mines, South Kensington, under Sir Harold Carpenter until 1927, when the investigation was taken over by the Department of Scientific and Industrial Research and continued at the Chemical Research Laboratory, Teddington, under Sir Gilbert Morgan. In the course of this work, which included early quantitative determinations of invisible oxide films on metals, a number of generalizations on atmospheric corrosion phenomena (ferrous and non-ferrous) has been established. Dr. Vernon's publications have included "A Bibliography of Metallic Corrosion" (Arnold), the first and second reports to the Atmospheric Corrosion Research Committee (each of which formed the subject of a general discussion by the Faraday Society) and numerous papers.

Awards of the Institution of Electrical Engineers

THE Council of the Institution of Electrical Engineers has elected Dr. Alexander Russell, principal of Faraday House Electrical Engineering College, to be an honorary member of the Institution. The Council has made the fifteenth award of the Faraday Medal to Prof. André Blondel, of Paris. The Faraday Medal is awarded by the Council of the Institution not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution.

International Congress on the History of Science

ON the occasion of the one hundred and fiftieth anniversary of the birth of Jan Evangelista Purkyně (or Purkinje), a distinguished Czech biologist, the fourth International Congress on the History of Science will be held in Prague on September 22-27. The Congress, under the presidency of Prof. Quido Vetter, will discuss papers dealing with (1) the development of the sciences during the eighteenth and first half of the nineteenth centuries; (2) the history of science in education; and (3) historical themes not included above. The contributions will not be restricted to the natural sciences only, medicine and the technical applications of science (for example, in agriculture) being also included.

Soviet Scientific Films

A MICRO-CINEMATOGRAPHIC study of the human capillaries is to be made by the medical cinematographic department of the Soviet Commissariat of Health. According to Mr. Volkof, the head of the department, the chief advantages of the scientific medical film in medicine lies in the possibility it opens up of modifying the time range of experiments to meet requirements. Action can be accelerated or slowed down at will. Moreover, the photomicrograph flashed on the screen frequently discloses many details unseen to the eye even with the aid of the microscope.

The Influenza Epidemic

THE Minister of Health has had special inquiries made through the regional medical officers of the Ministry into the local prevalence of the influenza epidemic. It appears that generally there is at present an extension from south to north, but that the distribution is patchy. Prevailing medical opinion is that the present outbreak, though widespread and highly infectious, is for the most part mild, most of the deaths being among the elderly. In the week ending January 9, there were 768 deaths ascribed to influenza in 122 great towns, as compared with 325 for the previous week, and the number of notifications of primary and influenzal pneumonia increased from 1,513 to 2,321.

The Night Sky in February

BETWEEN February 1 and February 28, the length of the night in the latitude of London decreases from $14^h\ 54^m$ to $13^h\ 13^m$. New moon occurs on February $11^d\ 7{\cdot}6^h$ and full moon on February $25^d\ 7{\cdot}7^h$. The planet Venus in the evening sky is a brilliant object; and in conjunction with the crescent moon on February $14^d\ 23^h$ will make a striking spectacle. On February 15 at 23^h, the planet will pass within $3'$ of the star δ Piscium (magnitude 4·6). Venus is at greatest elongation (47° E.) on February 5. Mercury is a morning star at greatest western elongation (26°) on February 7, when it rises about $1^h\ 12^m$ before the sun. On February 9 at 7^h, Mercury is in conjunction with the moon, the planet being 2° south of the latter. In mid-February, Saturn sets about two hours after the sun. On February 20, the plane of the rings passes through the earth, and the appearance of the ring system in large telescopes will be of special interest. In 1920 and 1921 when the system could be viewed in similar circumstances as will occur on February 20, it was found that the rings did not completely disappear—a fact which has a bearing on their thickness and structure. On February 13 at 15^h, Saturn will be in conjunction with the moon, the planet being 8° S. Jupiter rises near daybreak in the south-east; its magnitude is – 1·5. The most favourable times for observing the light changes of Algol (R.A. $3^h\ 04^m$, Dec. 40° 43′ N.) are as follows: February $2^d\ 2{\cdot}4^h$, $4^d\ 23{\cdot}2^h$, $7^d\ 20{\cdot}0^h$, $22^d\ 4{\cdot}1^h$, $25^d\ 0{\cdot}9^h$ and $27^d\ 21{\cdot}8^h$. The radiant for the α Leonid meteors on February 22–28 is at R.A. $10{\cdot}4^h$, Dec. 14° N.

Announcements

THE French Government has awarded the rank of Chevalier of the Legion of Honour to Prof. J. B. S. Haldane, professor of genetics, University College, London, for his scientific services to France.

PROF. ARTHUR HOLMES, professor of geology in the Durham Division of the University of Durham, has been elected a foreign correspondent of the Geological Society of America.

THE John Anisfield Award has been given to Drs. Julian Huxley and A. C. Haddon for their book "We Europeans: A Survey of 'Racial' Problems", with a chapter on "Europe Overseas" by Prof. A. M. Carr-Saunders, which was reviewed in NATURE of November 9, 1935, p. 736. The judges of the award are Prof. Henry Pratt Fairchild of the University of New York, Prof. Donald Young of the Social Science Research Council, and H. S. Canby of the *Saturday Review*. The prize is given for "a sound and significant book published in the previous twelve months on the subject of racial relations in the contemporary world".

AT the annual meeting of the New York Academy of Sciences held on December 21, the following honorary members were elected: Prof. K. S. Lashley, of Harvard University; Prof. Henri Breuil, professor of prehistory in the Collège de France; Dr. Julian S. Huxley, secretary of the Zoological Society of London; Dr. Aleš Hrdlička, curator of physical anthropology in the U.S. National Museum; Dr. A. C. Haddon, formerly reader in ethnology in the University of Cambridge; Sir Arthur Hill, director of the Royal Botanic Gardens, Kew; Prof. Maurice Caullery, professor of zoology (evolution) at the Sorbonne, and Prof. Octave Duboscq, professor of marine biology at the Sorbonne.

LORD NUFFIELD has given a silver trophy which will be awarded to the town or village collecting the most money, per head of population, for the annual Empire Day appeal for the British Empire Cancer Campaign. In 1931 Lord Nuffield gave £25,000 to the British Empire Cancer Campaign to be invested to provide a research fellowship at the Mount Vernon Hospital.

AT the annual meeting of the Royal Meteorological Society, held on January 20, the following officers were elected: ***President***, Dr. F. J. W. Whipple; ***Treasurer***, W. M. Witchell; ***Secretaries***, H. W. L. Absalom, W. Dunbar and E. L. Hawke; ***Foreign Secretary***, J. F. Shipley; ***New Members of Council***, Miss Elen E. Austin and R. S. Read.

A PRIZE of £20 with a diploma is awarded annually by the Royal Asiatic Society for an essay on a selected subject. The object of the competition is to encourage interest in the history and civilization of the East among non-Asiatics. Alternative subjects for 1937 are: (*a*) "Tamerlane" and (*b*) "The Relations of the Greeks with the East". Essays must be in the hands of the secretary by October 1. Further information can be obtained from the Secretary, Royal Asiatic Society, 74 Grosvenor Street, London, W.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 199.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Museums and their Type Specimens

IN NATURE of January 9 (p. 62), reference is made to a paper published by Dr. R. Broom in the *Annals of the Transvaal Museum* (18, 397–413; 1936), in which he complains that four type-specimens in the British Museum have been maltreated while being investigated by Dr. Boonstra; one, a type described by Owen, and the others by himself. Speaking generally of type-specimens, "in some cases," he says, "even the matrix ought not to be removed for sentimental reasons". He would scarcely permit a type "to be broken up in the interest of the morphologist. . . . But any museum which allows type-specimens to be cut in slices or to have parts ground away always seems to me to be guilty of a gross breach of trust". As for the British Museum, "apparently any visitor can cut up types in any way he fancies".

It is unlikely that many readers of NATURE will suppose the Trustees to be so careless of the collections as the last sentence suggests; nor will they be led astray by Dr. Broom's generalizations on the sectioning of type-specimens. But Dr. Broom should remember that the study of many groups of fossils, for example, Palæozoic corals, would be at a standstill, instead of (as indeed it is) going rapidly forward, if type-specimens were not sectioned as a matter of course. It is clear that it is for the responsible officers alone to decide to what extent it is desirable to develop or otherwise treat a type-specimen. Perhaps more surprising is Dr. Broom's attitude to morphology as shown by the remark quoted above. So long as the Natural History Museum is an institution of progressive research, as in fact it is, so long the type-specimen of a fossil species placed there has no value other than a morphological value. Palæontology is based on morphology, and to refrain from removing matrix from a type "for sentimental reasons" is to place a type fossil on a par with a mere personal relic.

Dr. Boonstra came to England in 1933 to study under Prof. D. M. S. Watson. He was then palæontologist to the South African Museum, and even at that time was noted for his experience and skill in developing Karoo reptiles. He could not, therefore, be described as "any visitor". In view of his known skill, and on the understanding that Prof. Watson was supervising his work, Dr. Boonstra was allowed to develop certain specimens, among them being those about which Dr. Broom complains. In Prof. Watson's opinion, Dr. Boonstra's work upon the specimens, far from having damaged them, has enhanced their value.

It may also be added that Dr. Broom has not seen the specimens since they were developed by Dr. Boonstra.

Prof. Watson allows me to quote his comments upon each of the four specimens concerned:

"(1) Owen's type of *Theriognathus microps*. Dr. Broom's claim is in effect that no old type should ever be re-prepared. This is an impossible position, held by no museum of importance in the world. The specimen (No. 47065) in its original state was undeterminable specifically, generically and *ordinally*! It was in fact entirely valueless. We do know now to what group it belongs. Its outer appearance has been very little altered by preparation.

"(2) The type of *Burnetia mirabilis* (R. 5697). This was described and figured by Broom when still covered with a coat of matrix. I began to prepare it, and found that the matrix coat was very irregular in thickness, so that its outer surface bore little relationship to that of the skull, and that the contact between bone and matrix was such that there would be no difficulty in making an accurate preparation. Sufficient flecks of matrix remain attached to the skull to show that Dr. Boonstra's preparation was well done, and that the present form of the skull is genuine.

"(3) The type of *Cerdodon tenuidens* (49420). The specimen is indeterminable. The exposed surface has not been touched at all by preparation. The attempts to cut a median section failed because so little of the skull was visible, and really amounts to no more than the removal of useless matrix. The specimen is completely incapable of preparation, since there is practically nothing but a weathered surface.

"(4) *Ictidosuchoides longiceps* (R. 5744). The information which can be gained from this specimen has been very greatly increased by Dr. Boonstra's preparation. Dr. Broom objects that Dr. Boonstra, by grinding away the edge of the maxilla, has destroyed two small canine teeth and removed all evidence of the shape of the maxillary margin. The technique of grinding faces on fossil skulls which are difficult to prepare was, I believe, first used extensively by Dr. Broom himself on Texan and S. African materials in the American Museum, and is sometimes of use. Dr. Boonstra's use of it on this skull was restrained and reasonable. He ground down into the lingual surface of the maxilla, so that its outer surface remains untouched, the margin being preserved. There is thus in my opinion no justification for Dr. Broom's strictures."

Electrical Stimulation of the Human Cochlea

It has been shown by Jellinek and Scheiber[1], and since confirmed[2,3,4], that stimulation of the human cochlea by audio-frequency alternating currents results in a sensation of tone corresponding in pitch to the frequency of the stimulus. The possibility that the mechanism of excitation is by direct stimulation of the cochlear nerve fibrils has an important bearing upon existing views on audition, in so far as it would provide clear evidence in support of the 'telephone' theory. It has been suggested as an alternative possibility that the electrical currents excite the nerve elements indirectly by setting in motion, in a manner not understood, those cochlear elements which are normally set in motion by physiologically applied sound waves. Such a mechanism of excitation would imply localization of the response according to frequency by resonance, and so would make possible an explanation of the observed phenomena upon the basis of the Helmholtz resonance hypothesis. This 'movement' theory of excitation is strongly supported by experimental evidence which is now described. As stated by Hartridge[5], sudden reversal in the phase of a continuous musical tone results in the human subject in a sensation described as a 'phase change beat'. This, in accordance with the resonance hypothesis, has been correlated with a transient arrest of the basilar fibres due to the opposition of the applied force following the phase reversal to the after swings due to resonance. Further, objective evidence of the occurrence of such an arrest has been provided by a recent study of the auditory tract potentials in the cat[6].

In the light of these findings, it has been considered justifiable to attribute the 'phase change beat' to the intervention of resonant moving parts between the nervous elements and the applied stimulus. The experimental demonstration of the occurrence of a 'phase change beat' in response to an electrical stimulus undergoing periodic phase reversal would therefore clearly be subject to the same explanation and so support the 'movement' theory of excitation. Stimulation of the human ear upon these lines has accordingly been carried out. The electrical output of the phase-reversing photo-electric siren already described[6] was used at a frequency of 1,024 ∼ with leads to the external auditory meatus (filled with saline) and to a metal plate on the forearm.

Under these conditions the phase change beat was found to be clearly observable. Further, the beat was heard at an intensity some 8 db. above that of the threshold for perception of the tone itself. This difference was found to approximate closely to that observed when the phase-reversing stimulus was applied to the ear mechanically, namely, by means of a moving-coil loud-speaker. This correspondence is considered to provide further evidence that the mechanism of excitation involved in the normal mode of audition is similarly involved by electrical stimulation. In addition, observations have been made upon the response of the human ear to interruptions of four and ten cycles duration in continuous tones of 1,024 ∼. Here also the stimulus was generated by a suitable modification of the photo-electric siren and was applied to the ear electrically and also by means of the moving-coil loud-speaker.

With an interruption of four cycles duration, the beat due to the interruption was observed at an intensity some 18 db. above that of the threshold for the tone itself. With an interruption of ten cycles duration, the difference between the beat and tone thresholds was smaller (10 db.), in accordance, presumably, with a change in ratio of the factors of intensity and duration of interruption which govern perception of the flicker of sound.

In all cases, the differences in threshold for tone and beat observed with the electrical mode of stimulation were found to approximate closely to the corresponding differences found by the mechanical mode represented by the loud-speaker method of stimulation.

This finding must again be considered to provide confirmation of the movement theory of excitation of the human cochlea by audio-frequency electrical stimulation.

Sir Grafton Elliot Smith and Work on Early Man in China

In looking back over the history of the research on early man in China, it is of interest to realize how precarious was the adventure we entered upon. At the present time, we have five more or less complete skulls, four large skull-fragments, twelve mandibles, and nearly one hundred isolated teeth—indeed an imposing 'sum' of specimens of *Sinanthropus*. However, the impressive point in this history is the fact that the vital generic characteristics of the distinct hominid were deduced from a diagnosis based, not upon this large number of specimens, but upon *one single molar tooth*. This specimen, which heralded a period of great scientific activity, was placed at our disposal in 1927 by the late Dr. Davidson Black.

After this birth of *Sinanthropus*, on account of the dearth of material and the difficulty of drawing conclusions from one isolated tooth, Dr. Black's claims were not everywhere accepted. It was Sir Grafton Elliot Smith who, as an authority in the field of early man, first accepted *Sinanthropus* as a distinct genus of the hominid; and it was Sir Grafton Elliot Smith who gave the needed support and impetus to Dr. Black, which encouraged him to carry on his scientific explorations in China.

The discovery of a skull in 1929 proved that *Sinanthropus* was not a product of Dr. Black's imagination, but that on the contrary he had been quite justified in his classification of a new genus in human palæontology. In November 1930, the Cenozoic Research Laboratory of the National Geological Survey of China invited Sir Grafton to take the long journey to the Far East in order to examine the new specimens and to visit the very site from which they had been taken. Thus it was Sir Grafton who, among all the anthropologists from outside the laboratory, was the first to handle the skull and to discuss it with Dr. Black.

After a painstaking examination of the specimens and a lengthy inspection of the site at Choukoutien, Sir Grafton announced his complete agreement with the geological and palæontological bases upon which the claims for the antiquity of *Sinanthropus* were based. Upon his return to England, Sir Grafton delivered a series of lectures and issued several important publications fully supporting our conclusions concerning the antiquity of *Sinanthropus*. Furthermore, he compared Peking man exclusively with early man from other localities, and stated his belief that the Lower Pleistocene man of China was contemporary with *Eoanthropus* and *Pithecanthropus*.

While it is a source of much gratification to realize that research on early man in China is being actively prosecuted, our joy in these achievements is lessened when we realize that the energetic promoter, the powerful protector, the kindly friend, of all these scientific investigations, Sir Grafton Smith, is gone. One hears frequent mention of the work of the members of the Cenozoic Laboratory—their research, their accomplishments—but it is doubtful whether their undeniably sincere efforts and scholarly achievements would have been so widely known and so quickly accepted but for the backing of such an authority as Sir Grafton. His approval naturally carried the greatest weight with European scientific workers.

After the sudden death of Dr. Davidson Black in May 1934, Sir Grafton grieved, not only for the loss of a friend, but also for the consequent setback to the search for early man in China. We in China suffered even more, because ours was the difficult problem of finding another anthropologist willing and capable of carrying on Dr. Black's half-finished task. It was Sir Grafton who, at the request of the director of the Geological Survey of China, and of the Rockefeller Foundation, recommended Prof. F. Weidenreich to succeed Dr. Black. We deeply appreciate the honour of having so wise and experienced an anthropologist as Prof. Weidenreich to carry on this vital research, but the thought is always foremost with us that it was Sir Grafton who introduced him to us.

In addition to material in his books, Sir Grafton wrote frequent articles concerning the search for man's ancestors in China, which were published in weekly or daily papers. Every fresh discovery made in China would be followed by a review of Sir Grafton's. His enthusiasm in his desire to help us surmounted even the unfortunate state of his health, which prevented him from writing much towards the last.

Very recently, having learned through a letter from me that we had requested the Rockefeller Foundation for a three-year grant, Sir Grafton wrote immediately, stating the importance of the continuation of our research work on early man in China. His appeal, written from the Queen Mary Hospital at Sidcup, appeared in *The Times* about a month before his death, and was undoubtedly influential in securing us continued financial support.

The death of Sir Grafton is indeed a signal loss to the entire scientific world. To us, in China, where the modern sciences are but newly and insufficiently developed, and where our need is great for the interest of authorities in other parts of the world, this new lack will be felt with especial keenness. We have lost, not only an ardent advocator, but also a sympathetic and well-loved friend.

A Condensing Monochromator for X-Rays

IT has long been recognized that some of the halos observed on X-ray photographs of liquids and amorphous substances may be spurious and due to the white radiation peak. Some of the observed reflections obtained from concentrated solutions of tobacco mosaic virus[1] were under suspicion for this reason, and the use of a nickel filter did not serve to resolve our doubts. Consequently, it was necessary to attempt to use monochromatic radiation. This was achieved as described below. As shown in Fig. 1, the use of monochromatic radiation decisively establishes the spurious nature of the innermost reflection.

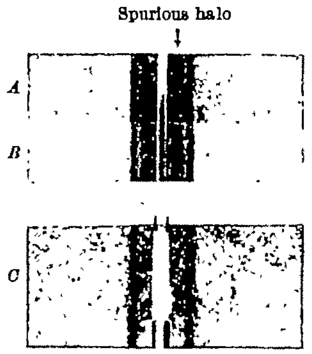

Fig. 1.
TOBACCO MOSAIC VIRUS. ELIMINATION OF SPURIOUS HALO BY USE OF MONOCHROMATIC RADIATION. *A*, UNFILTERED RADIATION, COPPER TARGET. *B*, FILTERED THROUGH 0·0005 IN. NICKEL FOIL. *C*, MONOCHROMATIC RADIATION. SPECIMEN TO FILM DISTANCE, 40 CM.

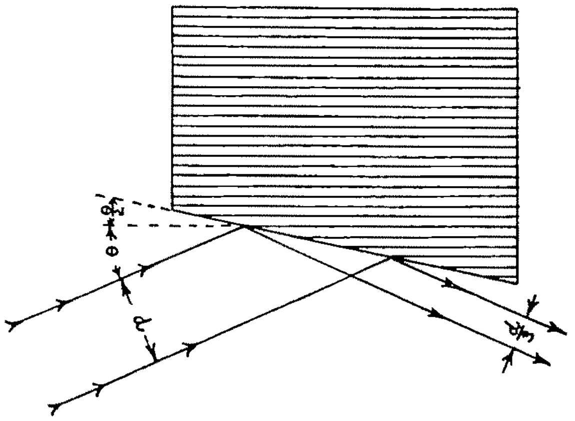

Fig. 2.
CONDENSING EFFECT OF SURFACE GROUND AT AN ANGLE $\theta/2$ WITH BRAGG PLANES.

As the exposure times necessary with the available X-ray sources, using a 0·0005 in. nickel filter, were of the order of 40 hours, it was obviously essential to develop a monochromator which would not increase the exposure time to prohibitive length. Stephen and Barnes[2] had suggested the use of single copper crystals cut at an angle of 40° with the 311 plane.

Such an arrangement, they suggested, would give a concentrated beam of polarized copper $K\alpha$ X-rays. This arrangement, to my knowledge, has not been tried. For the work in question, it was desirable to have a very intense source of comparatively unpolarized radiation. Various crystals were tested as monochromators and both cleavage surfaces and crystals ground as suggested by Stephen and Barnes were used. For all the crystals tested, the face was ground at an angle $\theta/2$ with the reflecting planes. For small Bragg angles θ, this should give a concentration of 3 : 1 (Fig. 2). It was thought desirable for two reasons to use a moderate concentration in these preliminary experiments, contrary to the suggestion of Stephen and Barnes, first to reduce the absorption of the reflected beam, and secondly because there was no need for a beam finer than the slit used.

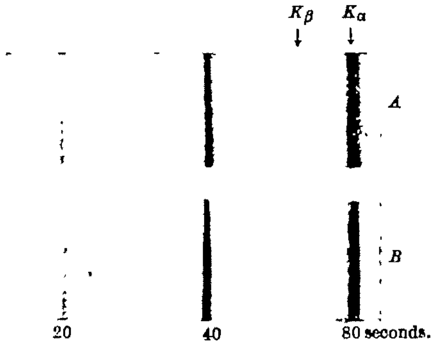

Fig. 3.

EFFECT OF GRINDING FACE OF PENTAERYTHRITOL CRYSTAL AT AN ANGLE OF 5° WITH CLEAVAGE SURFACE. *A*, GROUND SURFACE; *B*, CLEAVAGE SURFACE.

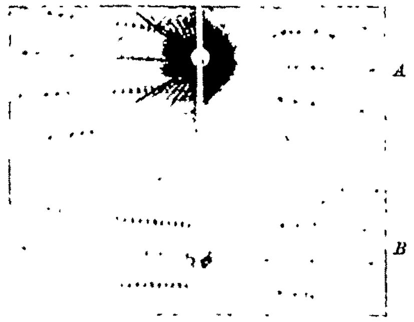

Fig. 4.

15° OSCILLATION PHOTOGRAPHS OF DI-HYDRO LUMISTEROL ACETATE. *A*, UNFILTERED RADIATION; *B*, MONOCHROMATIC RADIATION FROM GROUND FACE OF PENTAERYTHRITOL CRYSTAL. TIME, 3 HOURS; CRYSTAL TO PLATE DISTANCE, 3 CM.

In view of the success of these preliminary experiments, further work is in progress to determine the optimum angle of grinding for pentaerythritol, the crystal finally chosen. This can easily be obtained from aqueous solution in large crystals; it has a perfect *c* face cleavage, and the second order reflection is very intense. The Bragg angle is 10° for copper radiation, so the degree of polarization introduced into the reflected beam is not serious. Fig. 3 shows the concentrating effect of grinding the crystal so that the face makes an angle ($\theta/2$) of 5° with the reflecting planes. These reflections were obtained from a single pentaerythritol crystal, one side of which was a cleavage face and the other side ground as stated above. No slit was used and the crystal to film distance was 120 cm. The concentrating effect of the ground surface is very marked.

The same crystal was then set up as a monochromator using the ground surface, and test exposures made on an analysing crystal, di-hydro lumisterol acetate (Fig. 4, *A* and *B*). In *A* the direct unfiltered beam from a Philips Metallix copper tube was used, in *B* the monochromatic radiation. The same slit system was used, but with the monochromator, the front slit was removed as the monochromatizing crystal itself acts as a slit of very small width. If one takes into consideration the lack of background and the smaller size of the reflections obtained with the monochromatic radiation (with the possibility therefore of using a larger slit), it can be safely said that for equivalent intensity and size of reflection the use of a monochromator as described involves no appreciable increase of exposure time. Considering that these experiments were done very roughly and that optimum conditions were certainly not realized, it is not too optimistic to believe that work with monochromatic radiation can be done with the same ease as, or greater ease than, with heterogeneous radiation.

Layer-Line and Debye Photographs by means of the Characteristic X-Rays of the Crystal Itself

THE anomalous X-ray reflections from rotating crystals reported by Clark and Duane[1] and first ascribed to characteristic radiation of the crystal itself have since been regarded as due to other phenomena. The *Quellen-Strahlung* of W. Kossel[2] emitted by single-crystal anticathodes and found by G. Borrmann[3] on exciting the crystal with X-rays is not able, however, to account for the layer-line and Debye photographs produced by us[4] using either an X-ray source giving only 'white' radiation or a tube with copper or iron anticathode.

The photograph of a rotating crystal reproduced in Fig. 1 shows interferences among the ordinary reflections due to the copper K_α-radiation, which must be ascribed to the rubidium K-radiation of the crystal itself. A series of photographs has also been taken using rotating single crystals of cæsium nitrate and strontium sulphate, powdered rubidium salts and sodium bromide and copper, iron and zinc wires. In the Debye photographs of copper and iron wires using an aluminium anticathode, not only the well-known reflections due to the face-centred (Cu) or body-centred (Fe) cubic lattice were observed, but also reflections corresponding to the simple cubic lattice. Using an ordinary X-ray tube with copper anticathode these 'forbidden' reflections, though faint, could still be observed in the Debye photographs of a copper wire.

The last fact makes it rather probable that the new effect is partly due to the direct interference of the characteristic radiation emitted by the excited atoms, this radiation thus showing a certain degree of coherence. It is clear, however, that a secondary interference of the primary fluorescence radiation must play a part, since a crystal of ammonium nitrate embedded in bromoform and rotating in a beam of 'white' X-rays gave a layer-line photograph of the crystal in question corresponding to the wave-length of bromine K-radiation. As to the question of the coherence of the fluorescence radiation, the modern view on the exciting act makes a certain degree of coherence rather plausible.

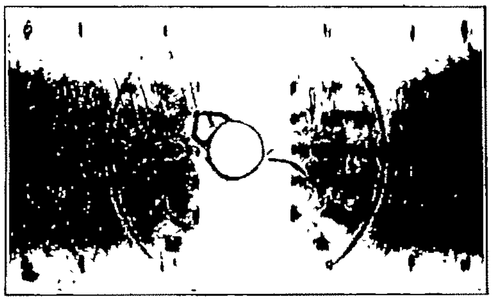

Fig. 1.

We shall deal in a more detailed way also with the theoretical side of the effect in a forthcoming communication.

The Existence-Range of the β Hume-Rothery Phases

FROM the data given in Dr. Hansen's recently published elaborate work[1], "Equilibrium Diagrams of Two-Component Alloys", and various other original diagrams, I have tried to find some regularities in the existence-ranges of the β Hume-Rothery phases. The term 'existence-range' indicates that range (expressed by the valency electron concentration) which lies between the maximum and the minimum solid solubilities of the second component in β phases. The accompanying table was obtained. (In this table, the maximum solid solubility in α solid solution and the minimum solid solubility in γ phase are also given.)

The following conclusions can be drawn from this table.

(1) When the atomic size factor is favourable for the formation of electron compounds[2] (Hume-Rothery phases)—according to Hume-Rothery, the size factor is favourable, as long as the difference of the atomic diameters of two components is kept within 15 per cent—the existence-range of the β Hume-Rothery phases are, approximately, 1·37∼1·57 for zinc alloys, 1·42∼1·58 for cadmium alloys, and 1·38∼1·62 for aluminium alloys, respectively. It is a very interesting fact that the existence-ranges are approximately constant, where the second component is the same. For example, in copper-zinc, silver-zinc and gold-zinc systems, the ranges show approximately constant values, namely, 1·37∼1·57.

(2) When other factors[2] (such as size factor, negative valency effect, etc.) are favourable, the maximum solid solubility of the second component in α solid solution is a little greater than the minimum solid solubility of the same component in β phase, as can be seen in the systems copper-zinc, silver-cadmium, copper-aluminium, and silver-aluminium. Hence the existence-ranges of α- and β-phases overlap by a few atomic per cent (in most cases 1 per cent). For example, in the copper-zinc system, the maximum solid solubility of zinc in α solid solution and the minimum solid solubility of zinc in β phase are 38 and 37 per cent, respectively.

A similar relation is likely to be found in the existence-range boundaries of β and γ phases, although with less accuracy.

M. HARA.
Institute of Metallography,
College of Science,
Kyoto Imperial University,
Japan. Nov. 7.

System	Difference of atomic diameter (per cent)	Maximum solid solubility in α-phase (atomic per cent)	Maximum solid solubility in α-phase (valency electron concentration)	Existence-range of β-phase (atomic per cent)	Existence-range of β-phase (valency electron concentration)	Minimum solid solubility in γ-phase (atomic per cent)	Minimum solid solubility in γ-phase (valency electron concentration)
Cu–Zn	+ 7·7	38	1·38	37 ∼ 56	1·37 ∼ 1·56	57	1·57
Ag–Zn	– 4·7	38	1·38	38 ∼ 57	1·38 ∼ 1·57	60	1·60
Au–Zn	– 4·5	31	1·31	36 ∼ 57	1·36 ∼ 1·57	64	1·64
Cu–Cd	Size factor is not favourable.						
Ag–Cd	+ 5·5	43	1·43	42 ∼ 57	1·42 ∼ 1·57	57	1·57
Au–Cd	+ 5·7	36	1·36	43 ∼ 58	1·43 ∼ 1·58	61	1·61
Cu–Al	+ 10·9	20	1·40	19 ∼ 31·5	1·38 ∼ 1·63	31·5	1·68
Ag–Al	– 1·8	20·6	1·41	19·7 ∼ 31	1·39 ∼ 1·62	—	—
Au–Al	Existence of β Hume-Rothery phase is doubtful.						

Remarks on the table.

1. As the numerical values of the atomic diameters, those[2] given by Hume-Rothery are used.
2. All the numerical values of the atomic percentage indicated are those of the second component in each system.
3. "Valency electron concentration" means the ratio "valency electrons : atoms".
4. The negative sign of the difference of the atomic diameters means that the atomic size of the second component is less than that of the first component, and the positive sign means that the former is greater.

Assimilation of Different Organic Substances by Saprophytic Flagellatæ

THE ordinary sewage flagellate, *Polytoma uvella*, which contains no chlorophyll, is, as I showed in 1920[1], an acetate organism. It builds up its body and the starch abundantly deposited in it from fatty acids, while it cannot utilize sugars. Since *Polytoma* lives in decaying protein solutions, I concluded that amino acids must be hydrated under desamination to supply to the *Polytoma* its specific food. In the meantime, it was shown that fatty acids, and especially acidic acid, are very important for the nutrition of micro-organisms. I have investigated a number of organisms with life conditions more or less similar to those of *Polytoma*—pigment-free forms from groups nearly related to those assimilating carbon dioxide[2]. I found that in all cases acetate is the food-substance preferred. These micro-organisms belong to three series of flagellatæ, rather removed from each other systematically, namely, Phytomonades, Cryptomonades and Euglenomonades (see table). The first two deposit starch, the last one the similar polysaccharide 'paramylum'.

	PHYTOMONADES						CRYPTOMONADES			EUGLENOMONADES		
	Polytoma uvella	*Polytoma ocellatum* (1)	*Polytoma ocellatum* (2)	*Polytomella caeca*	*Chlorogonium euchlorum*	*Hyalogonium Klebsii*	*Chilomonas oblonga* (1)	*Chilomonas oblonga* (2)	*Chilomonas paramecium*	*Euglena gracilis*	*Astasia quartana*	*Astasia (Chattonii) longa*
Acidic acid	+	+	+	+	+	+	+	+	+	+	+	+
Propionic acid	−	−	+	+	−	−	+	−	−	+	+	+
n-Butyric acid	+	+	−	+	−	−	+	−	−	+	+	+
n-Valerianic acid	−	+	−	+	−	−	+	−	−	+	−	−
n-Capronic acid	−	−	−	−	−	−	−	−	−	+	−	−
i-Butyric acid	−	+	+	+	−	−	+	−	−	−	−	+
Ethyl acetate	+	+	+	+	+	+	+	+	+	+	+	+
Ethylal	−	−	−	+	−	−	−	+	+	+	−	+
Malic acid	−	+	−	−	−	−	−	−	−	+	−	+
Lactic acid	+	+	−	+	−	−	−	−	+	−	−	−
Pyruvic acid	−	−	−	−	−	−	+	−	−	−	−	−
Succinic acid	+	+	−	+	+	+	+	+	−	+	+	+
Glycerine aldehyde	−	−	−	−	−	−	−	+	−	−	−	+
Dioxyacetone	−	+	+	+	−	−	+	−	+	−	−	−

Up to date, I have results for twelve forms, to which *Peptone de viande Vaillant* in the presence of about twenty different organic substances was offered in solution. With peptone alone as well as with formic, oxalic and lævulinic acid, with glycol, glycolic acid, glycerine, pentoses and hexoses in case of small inoculation only a very small or no development at all was observed. With the other substances, the micro-organisms behaved in very different ways. Only acetate was favourable in all cases, and so too ethyl acetate. The homologues of acetic acid are not so generally accepted: the longer the carbon-chain the more rarely the fatty acids are assimilated.

Special importance is attached, therefore, to newer results with succinic acid. The trioses are, contrary to the hexoses, assimilated by some species, and also such substances as ethylal, malic, lactic and pyruvic acids, but not so often as succinic acid. In a similar way to that in which acetic acid is formed from glycine, succinic acid is formed from asparaginic acid in the putrification of proteins by reduction and splitting off of ammonia. Also, the dehydration of acetic acid with condensation of two molecules may be considered as a source for succinic acid. This appears to me important to the conditions of life in the natural environment of the pigment-free flagellatæ. Here, succinic acid may be formed in putrifying mud, rise into the oxygen-containing water layer and there be used by the flagellates. Probably this acid plays, in general, a more important role in nutrition than at present known.

Especially strong was the growth of a *Chilomonas* species with succinic acid salts, here even as great as with acetate. In the course of many nutrition experiments, more rapid and abundant growth has not been observed. Succinic acid may consequently be regarded as the specific nutrient for this organism, from which it builds up its body and forms a considerable quantity of starch in pure cultures.

Adrenal Degeneration in a Pure Strain of Mice subject to Mammary Cancer

WE have observed as a regular occurrence spontaneous degenerative changes in the adrenals of both males and females of a genetically pure strain of mice. The strain is the *R* III strain obtained by Mme. Dobrovolskaia-Zawadskaia of the Institut du Radium in Paris as the result of brother and sister mating and maintained in our laboratory in this way for the last three years. The degenerative changes in the adrenals are progressive, and when fully developed at the age of about one year are massive and involve both cortex and medulla. The degenerative changes are of a specific kind and have never been seen by us to occur spontaneously in the adrenals of mice of mixed strains up to one year of age, of which we have examined more than a thousand.

The following considerations add to the interest which these findings may have from the point of view of genetics: (1) The genetically pure strain *R* III in which these degenerative changes occur has a high incidence of spontaneous mammary cancer in the females. (2) In the males of this strain, which never develop mammary cancer spontaneously, a high incidence of mammary cancer can be induced by the continued administration of œstrin. (3) The degenerative changes in the adrenals, which set in spontaneously in the mice of the *R* III strain, are identical with the degenerative changes in the adrenals which we have recorded[1] as developing regularly in male and female mice of mixed strains after the continued application of œstrin.

A detailed account of these observations will be published soon.

Wing Abnormality in *Locustana pardalina*

I ENCLOSE photographs (Fig. 1) of two locusts with the following history: The eggs were hatched and the young reared inside, in glass, so that the only sunlight that could reach them was screened through two layers of glass; other conditions were identical with such as produced perfectly normal flyers. They remind one strongly of similarly localized (and similarly produced?) abnormalities in *Drosophila*, and we may legitimately assume that the abnormality will be hereditary.

Most of the young were used for experimental purposes, but eleven remained over by the time that they were ready to undergo the final moult. Of these, three died immediately after the moult, the wings remaining small and crinkled. Four survived the moult but with wings as in the photographs, and four were apparently perfectly normal.

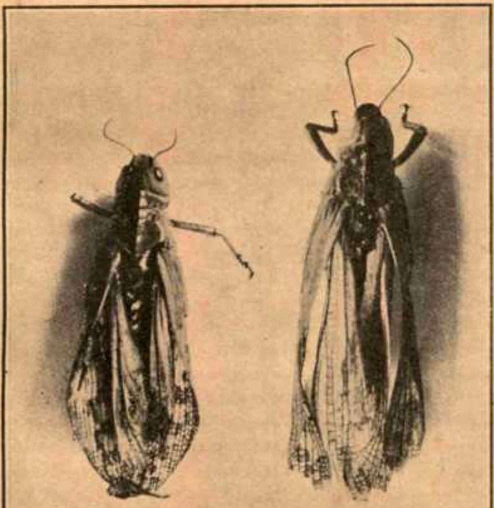

Fig. 1.

LOCUST WITH ABNORMAL WINGS. THE LEGS OF BOTH SPECIMENS WERE BROKEN OFF AFTER DEATH.

About a fortnight after the moult, the eight locusts were sprayed with a suspension of a *Micrococcus* sp. in the form of a fine mist: all four abnormal locusts died (the first two, the last nineteen days after infection); the four normal ones are still alive. The course of infection is the same in all—the fæcal pellets, 24 hours after infection, were in the mornings red, jelly-like and swarming with *Micrococcus*; after feeding, the pellets become more or less normal with only a light infection. The live ones are still (nearly a month after infection) passing such pellets. In those that died, the rectal matter suddenly became a very acid, brown, slimy liquid with a massive *Micrococcus* infection.

The abnormal wing character is thus associated with a loss of constitutional vigour, the latter being revealed by non-survival of the last moult and by decreased resistance to bacterial attack. This is, of course, no new phenomenon; idiocy in man is almost constantly associated with small bodily size, a short expectation of life and an increased susceptibility to disease.

Cases such as these add force to the objections that have been raised against the mechanistic preformationalism of modern genetics; they indicate in no uncertain way that the injuries concerned are of a constitutional character—injuries of the organism as a whole—which may be expressed as definitely localized abnormalities, perhaps particularly in the latest ontogenetic developments; they seem to indicate that genetics deals not with primary and independent but with secondary phenomena, dependent on, or modifying, 'holistic' changes.

McCormick and the Reaping Machine

IN NATURE of December 26, p. 1088, a note appears referring to twelve notable American inventions. Among these is included a practical reaping machine by Cyrus McCormick. Cyrus McCormick was not the inventor of the first practical reaping machine. No doubt the American firms concerned with the manufacture of reaping machines have loudly and persistently claimed McCormick as the inventor of the reaping machine, and some British writers, who should have known better, have accepted this claim, but it has been repeatedly disproved that McCormick has any claim to be considered the maker of the first practical reaping machine.

Early in the nineteenth century there were many attempts to make reaping machines, and some of these attempts attracted considerable attention. The first really practical machine which was able to cut a harvest and continue to do so year after year was made by the Rev. Patrick Bell, in 1828, when he was a divinity student at the University of St. Andrews. A full account of this machine was published in 1828 in the *Quarterly Journal of Agriculture*. The original machine, which Bell made with his own hands with the assistance of the local blacksmith, is now in the Science Museum at South Kensington. This machine was used on the farm of Bell's father and afterwards on the farm of his brother for many years.

The earliest year in which it is claimed that McCormick produced a reaper is 1831, but no proof can be produced to show that he made any machines until several years later. By that time several of Bell's machines had found their way to America.

It is claimed on behalf of McCormick that Bell never patented anything whereas McCormick took out his first patents in 1834, and further patents in 1845 and 1847. Bell's reasons for not patenting anything have been given to us by himself and were of the highest and most honourable kind. He considered it to be his duty to present his invention freely to the agricultural public and not to add to its cost by any royalties or profits accruing to himself. He tells us that "The late Lord Panmure, knowing the low state of my finances, offered to be at the expenses of the patent if I would accept one. For the reasons above stated, I declined his lordship's offer". In later life, Bell admitted that it was probably a mistake that he did not patent his invention. As he gave it freely to the public, many imitations were turned out. He himself says, "Had I patented the machine at the time, all this bungling in machine-making would have been avoided; and the issue perhaps proves that, for the public benefit even, this was the prudent course to have been adopted".

Bell's machine embodied all the main features of the modern reaping machine though in a somewhat crude form. All these features were also included in the earliest known machines which could be ascribed to McCormick, but before McCormick's machines were made several of Bell's machines were already in America. McCormick's patents were disputed in his own country and prolonged law suits took place with regard to them.

Gesture Language

A PARAGRAPH in the Research Items in NATURE of December 5, entitled "Origins of Speech and the Orang-Utan", refers to Dr. Cornelius J. Connolly's important studies of the brains of various primates. The note stated that it is believed by neurologists that the associative process, with the power of making articulate sounds, constitute the essential elements in human speech, and that the association between sound and objects makes symbolism possible.

May I point out that human power of symbolism is not primarily dependent on association between *sound* and objects, but rather on the ability (which apparently is peculiar to man) of analysing events—whether sensed or imagined—and expressing the separated elements by a series of separate bodily gestures.

The association between sound and objects (except in the comparatively rare onomatopœic symbolism of objects or events which are naturally associated with a characteristic and imitatable sound) came later; it probably arose—as I have previously pointed out—from the natural sympathy of movement between man's hands and his mouth which Charles Darwin described in "The Expression of the Emotions".

It is not generally known that the natural pantomime of uneducated deaf mutes, by which the born deaf of all nations can communicate with one another, is not built up of separate signs equivalent to words. It does not analyse events into separate parts equivalent to parts of speech; it cannot define. It would appear that man's advance was primarily due to his development of this power of symbolism —which made new syntheses possible.

The original pantomimic expression of primitive man was doubtless accompanied by an emotional gabble—due to the Darwinian association of hand and mouth, and to the corresponding association of facial gesture and muscular movements of the larynx and pharynx which was assumed by E. B. Tylor[1] and which I have personally observed.

This 'gabble' can scarcely have been understandable by ear, for if the hand gestures were not standardized, the associated sounds could have no constant meaning. It was only when man had learnt to use a particular gesture to symbolize a definite object, action, quality, etc., that true speech began.

The chimpanzee fails in two respects: he cannot apparently symbolize, and his tongue does not move in sympathy with his hands. Thus, Madame Kohts[2] points out that whereas the young child feels with his hands and his tongue, the young chimpanzee feels with his hands and his lips.

In attempting to locate the areas of the brain responsible for the development of speech, the physical anthropologist should, I suggest, study especially those areas which control bodily gesture on one hand, and those which give the power of analysis on the other.

Neutrino Theory of Light

PROF. V. FOCK[1] has pointed out an apparent inconsistency in the neutrino theory of light. He shows that the operator of Jordan

$$\sqrt{|\nu|}\,b(\nu) = \sum_{\alpha=-\infty}^{\alpha=+\infty} \gamma^{+}(\alpha)\gamma(\alpha+\nu) \qquad (1)$$

commutes with his adjoint operator $b^{+}(\nu) = b(-\nu)$, while according to Jordan the relation

$$b^{+}(\nu)b(\nu) - b(\nu)b^{+}(\nu) = -1 \text{ for } \nu > 0 \qquad (2)$$

should hold. In configuration space the operator takes the form $\sqrt{|\nu|}\,b(\nu) = \sum_{k=1}^{k=n} b(\nu,x_k)$. k denotes the co-ordinate of the kth particle. Fock identifies the operators $b(\nu,x^k)$ with $e^{i\nu xk}$. Therefore all the $b(\nu)$ and $b^{+}(\nu)$ commute in contradiction with (2). However, a configuration space representation of a problem is only possible *if the number of neutrinos n is finite*. As we need the interpretation of Dirac with respect to the filled up negative energy states ($\alpha < 0$), we are concerned with an *infinite number of particles*.

If we assume *the number of possible states finite*, a configuration space description of $b(\nu)$ is possible, because the number of neutrinos is *a fortiori* finite. Let therefore $u_a(x)$ be the wave function of a state α. α takes all integral values between $-A$ and $+A$, where A is a finite positive integer, which tends towards infinity. The operator $b(\nu,x_k) = b^{+}(-\nu,x_k)$ is defined by

$$b(\nu,x_k)u_a(x_k) = \begin{cases} u_{a-\nu}(x_k), \text{ if } -A \leqslant \alpha - \nu \leqslant A \\ \quad 0\ , \text{ for all other values of } \alpha - \nu \end{cases} \qquad (3)$$

Let

$$\psi(\alpha_1, \ldots \alpha_k \ldots) = \sum_P \delta(P) u_{a_1}(x_1) u_{a_2}(x_2) \ldots u_{a_k}(x_k) \ldots u_{a_n}(x_n),$$

with $\delta(P) = \pm 1$ an antisymmetric wave function. The sum is to be extended over all permutations P. An easy calculation leads to the identity

$$\nu\{b^{+}(\nu)b(\nu) - b(\nu)b^{+}(\nu)\}\psi = \psi\left\{\sum_{a=A-(\nu-1)}^{a=A} N_a - \sum_{a=-A}^{a=(\nu-1)-A} N_a\right\} \text{ for } \nu > 0 \qquad (4)$$

$N_a = 1$ or 0 according to whether the particular α occurs or does not occur in $\psi(\alpha_1 \ldots \alpha_n)$. If the number of states tends to infinity and the total energy of the system remains finite, the Dirac interpretation demands that all states whose energy is smaller than a finite negative energy $-B$ are occupied ($N_\alpha = 1$ for $\alpha < -B$), while all states of positive energy above a certain positive energy B are empty ($N_\alpha = 0$ for $\alpha > B$). If ν is a finite positive integer, and if A tends to ∞, the first sum in the right hand term disappears and the second one equals ν, which is the desired result (2).

Nigeria and the Sahara

SOME passing remarks in the article entitled "Soil Drift in South Australia" in NATURE of December 19 (p. 1039) may give the casual reader the erroneous impression that the northern part of British Nigeria is threatened by the "encroaching desert". A glance at any adequate map of Africa will show that the northern frontier of Nigeria runs through the western Sudan and that the Sahara lies well to the north in French West Africa. The geological evidence is clear, as I pointed out twenty-five years ago[1], that the desert pulsates, that its margins expand and contract, and that the most recent movement has been one of contraction with the consequent spread of more humid conditions over the country between Lake Chad and the River Niger. There is no evidence that existing climatic conditions are deteriorating.

There may be room for some adjustment of stocking policy, but comparison with the Dominions is to be deplored. It should be remembered that in Nigeria the Africans themselves are the stock farmers, following ancient methods in unfenced communal pastures. They are happy and contented, and problems arise only when the industry is unduly stimulated by ambitious administrators or ardent tax collectors.

Points from Foregoing Letters

REFERRING to criticisms by Dr. Broom, the Keeper of Geology in the British Museum (Natural History) defends the removal of matrix and the sectioning of type-specimens in museums, in the interests of morphological research. He quotes Prof. D. M. S. Watson to show that the value of the fossil reptiles referred to by Dr. Broom were in no way impaired, but rather enhanced, after their treatment by Dr. Boonstra.

New experiments on sound 'beats' produced in the inner ear (by means of electrical stimuli, undergoing periodic phase reversal) are considered by C. S. Hallpike and Prof. H. Hartridge to supply additional evidence in support of the Helmholtz hypothesis, which postulates indirect excitation of the nerve elements by a resonance mechanism.

Preliminary results obtained by means of a new technique in utilizing monochromatic X-rays in crystal analysis are described by Dr. I. Fankuchen, and photographs are submitted indicating the spurious nature of the innermost halo observed in ordinary spectrograms of tobacco virus. Crystals of pentaerythritol ground at a suitable angle were found convenient for the purpose of increasing the concentration of the monochromatic X-rays.

An X-ray photograph of a rotating crystal, showing interference phenomena, is submitted by Chr. Finbak and Prof. O. Hassel. The authors consider that the effect is partly due to direct interference of the characteristic radiation emitted by the excited atom, and that a secondary interference of the primary fluorescence radiation also plays a part in the phenomenon.

A table showing the concentration ranges in which 'electron compounds' ('Hume-Rothery' phases) are formed in binary alloys of various metals (zinc, copper, silver, gold, cadmium, aluminium) is supplied by M. Hara. The existence ranges and also the solubility in the α and γ solid phases are considered by the author in relation to the difference in the atomic diameters of the components.

Various non-pigmented one-celled organisms (flagellates) have been grown by Prof. E. G. Pringsheim in peptone medium to which various organic substances (fatty acids, esters, etc.) were added. All organisms investigated thrived on acetic acid and on ethyl acetate but differed in their ability to assimilate other compounds. Succinic acid was also used by a large proportion of the organisms, and malic, lactic and pyruvic acids to a lesser extent.

A pure strain of mice in which degenerative changes in the adrenal glands develop spontaneously before the animals are one year old have been found by Dr. W. Cramer and E. S. Horning to be likewise very susceptible to cancer. The females have a higher rate of spontaneous mammary cancer, and in the males mammary cancer can be induced by administration of the sex hormone, œstrin.

Photographs of two locusts with abnormal wings, reared under glass in conditions which usually produce normal flyers, are submitted by Prof. T. F. Dreyer. The abnormal individuals also show lower resistance to micrococcus infection, indicating that wing abnormality is associated with changes in the organism as a whole. This, the author claims, supports the 'holistic' view of genetics.

Referring to the early history of the reaping machine, Prof. James Hendrick states that the Rev. Patrick Bell of St. Andrews built a practical reaping machine in 1828, several years before McCormick took out his patents in the United States.

Sir Richard Paget writes that the symbolism of human speech is not primarily dependent on association between sound and objects, but arose after man had succeeded in analysing events and expressing the various components by separate bodily gestures.

Referring to recent criticism by Prof. V. Fock of the neutrino theory of light, Prof. E. G. C. Stueckelberg states that, while a configuration space representation of operators is impossible, if the number of particles concerned is infinite, there exists a configuration space method for a finite number of particles, which leads in the limit to Prof. Jordan's result.

Research Items

Submerged Archæological Sites on the Essex Coast

A SUB-COMMITTEE of the Fenland Research Committee, of which Mr. S. H. Warren has acted as chairman, has been engaged on the investigation of the submerged land-surface of the Essex coast and has presented a report (*Proc. Prehistoric Soc.*, 2, 1) dealing with the character of the land-surface, the archæological sites, pollen analysis, pottery, and flint implements, and discussing the relation of this area to the East Anglian fenland, where broadly the same sequence of events—a period of land elevation followed by one of subsidence—has been established. The main archæological sites, three in number, are situated at Lion Point, Clacton (now Jaywick Sands), Mill Bay, Dovercourt, and Stone Point, Walton-on-Naze. They consist of surface settlements, or camp sites, pit dwellings, cooking holes and hearth sites. The old land surface can be seen at various levels below high-tide, and extends below the lowest level of spring-tides. It belongs, therefore, to a period of relative land elevation. The earliest trace of human habitation belongs to the Mesolithic III culture Windmill Hill pottery, leaf arrow-heads and flint and stone celts, belong to a Neolithic *A* people, who settled on this surface and were responsible for cooking-holes, pit-dwellings and hearths. They were followed by a Neolithic *B* people ; but judging from the relative scarcity of their pottery, they were in small numbers. The latest dateable material from the old land surface consists of a few beaker *B* sherds ; but no *A* beakers and no Bronze Age cord-impressed ware has been recorded. The human occupation of the land-surface seems to have come to an end with the onset of salt-marsh conditions. Over a peat bed, rich in pollen of Chenopodiaceæ, a layer of *Scrobicularia* clay indicates submergence. At Lion Point, Clacton, quantities of grooved ware, showing affinities with two types of Dutch megalithic ware, were found, and are now recognized for the first time to occur over extensive areas in south-eastern Britain.

Effect of Tissue Extracts on Tumour Growth

DR. J. B. MURPHY, of the Rockefeller Institute for Medical Research, summarizes his results on the inhibition of malignant growths by extracts from normal tissue in a paper in the "Reports of the Second International Congress of the Campaign against Cancer" (Brussels, 1936). Extracts of placenta, embryo skin and prelactating mammary gland inhibit the growth of transplanted mouse cancer when the graft is treated with the extract. The prelactating mammary gland, which appears to be the best source of the inhibiting agent, also contains a stimulating factor which is ether-soluble, while the inhibiting agent is water-soluble. In another paper in the same volume, Prof. T. Maisin and Dr. Y. Pourbaix describe the effects of feeding different animal organs on the growth of tumours induced in mice with benzpyrene. These organs contained both activating and inhibiting factors in different proportions. Whole liver had an activating action while whole brain was inhibitory. These factors, however, are probably different from those of Dr. Murphy, as the inhibiting factor was ether-soluble and the stimulating factor was water-soluble. The work described in the two papers indicates how complex is the control of tissue growth in both normal and malignant tissues in the living animal.

An Interesting Larval Bivalve

THE embryonic and larval stages of a Japanese species of *Sphærium* have been described by Dr. Katsuhiro Okada ("Some Notes on *Sphærium japonicum biwaense* Mori, a Freshwater Bivalve. (4) Gastrula and Fetal Larva". *Sci. Rep. Tôhoku Imp. Univ.*, Fourth Series (Biology), Sendai, Japan, 11, No. 1 ; 1936). There is no free-swimming stage, the whole of the embryonic and larval period being passed in the marsupial sac of the mother. The new term 'fetal larva' is given to the larval stage after the complete closure of the blastopore up to the formation of the rudimentary shell. This is quite different from a 'veliger', for the larva continues to develop until the small but adult form is reached without any sign of metamorphosis. This 'fetal larva' is, however, regarded by the author as a vestigial veliger. Most lamellibranchs develop as free-swimming veligers and pass through the larval stage with a simple velum and bivalve shell ; but there are several instances of the veliger stage being suppressed, especially in freshwater forms with viviparous habit. Compared with other lamellibranchs, the present species indicates signs of secondary direct development in which the metamorphosis is indistinct, merely the earlier development of the foot and the vestigial signs of the head region having been shown.

New Varieties of Potato

AN important application of Vavilov's geographical method in the study of economic crops has recently been made by Russian plant breeders with regard to the potato. The results of their work have been published mainly in Russian, and the bulletin issued by the Imperial Bureau of Plant Genetics (School of Agriculture, Cambridge, price 3*s.* 6*d.*), on "The South American Potatoes and their Breeding Value" can be considered as the first comprehensive account in English of one of the most remarkable discoveries in plant breeding. It describes the material collected on expeditions made to South and Central America, the original home of the potato, where more than twelve cultivated, and thirty wild species were found in place of the single cultivated species previously known. The properties exhibited by these forms have already provided a great stimulus to potato-breeding and, among other developments, should result in the crop being grown over a much wider geographical range than has been possible up to the present, for at least one species has been found which forms tubers under sub-tropical conditions, while others occur that can withstand frost. Disease resistance, short dormancy and high protein content are further valuable properties exhibited by these newly discovered forms, that will provide the breeder with new and valuable possibilities.

Sand Devils

THERE is not much detailed information in books on climatology or meteorology about the small pillar-like whirlwinds known as sand devils. It is common knowledge that they develop in deserts when the sun is strongly heating the ground, that is to say, especially in the summer, and then most often during the hottest hours of the day. Observers at the chain of meteorological stations of the Air Ministry that extends from Egypt to Iraq and the Sudan have had them under observation, however, since 1927, and a note entitled "Sand Devils", by W. D. Flower (Professional Note No. 71 of the Meteorological Office, Air Ministry), tells us what they saw and ends with a theory of their structure and formation that takes into account the instability of the lower atmosphere under intense solar radiation. The observed facts are briefly as follows: No marked preference for either clockwise or counter clockwise rotation was found. The way that they favoured the hottest part of the day was very marked, although observers are not prone to be abroad at that time and tend to miss many of those that develop then. Some observations of the linear speed of rotation at the outer edge were made and showed a range from 10 to 40 miles per hour. In size they varied from less than 5 feet to more than 2,000 feet in height, and from less than 5 feet to more than 200 feet in diameter. One might instance a diameter of 30 feet and a height of 200 feet as being the size of a typical sand devil, and less than one minute as its duration, although several lasted for ten or fifteen minutes. A super-adiabatic lapse-rate in the lower atmosphere appears to be usually, if not invariably, present. The sand devil of necessity travels with the general wind in its neighbourhood and demonstrates the normal increase of wind with height by leaning forwards in the direction towards which the wind is blowing.

Centimetre Radio Waves

A NOTE in the *Physical Review* of December 1 (50, 1091) by Messrs. C. E. Cleeton and N. H. Williams, of the University of Michigan, describes an investigation undertaken to determine the practical short-wave limit for electrical oscillations produced by valves. Three valves of the split-anode magnetron type were designed to operate at wave-lengths less than 2 cm. The smallest of these was provided with an anode of 0·038 cm. diameter, while the outside diameter of the glass envelope was 0·45 cm. At an anode voltage of 1,200 and with a magnetic field strength of 24,000 oersteds, oscillations were obtained at a wave-length of 0·64 cm., as measured with an echellette grating spectrometer previously described by the authors (*Phys. Rev.*, 45, 234–237; 1934). The resulting radiation was detected with a crystal detector placed at the focus of a receiving mirror at a distance of 15 metres from the valve. The other two valves produced oscillations of wave-lengths 1·2 cm. and 1·9 cm. at lower intensities of magnetic field. It is concluded that continuous electric waves may be produced at wave-lengths less than 1 cm., the waves being of sufficient intensity for many research purposes. According to a note recently received from Science Service, these minute radio waves are being used for the study of the molecular structure of gases, including water vapour. While such substances as black paper, ebonite and wood are transparent to the waves, it appears that their absorption by the water vapour in the atmosphere is such as to render their application to radio communication somewhat difficult.

Lightning and Overhead Transmission Lines

AT a meeting of the Institution of Electrical Engineers on January 7, a paper on "Lightning" was read by Mr. B. L. Goodlet. The first part of this paper dealt with lightning as a physical phenomenon and reviewed present knowledge and hypotheses on the formation of thunderclouds and the mechanism of the lightning flash. It was pointed out that a complete flash usually consists of a sequence of double strokes separated by time intervals of the order of one hundredth of a second. These double strokes comprise a preliminary or 'leader' from cloud to ground followed by a powerful 'return' stroke from ground to cloud. The distribution of flashes to earth under a storm centre is influenced by the distribution of space charge above the ground and by discontinuities of conductivity in the ground itself. The second part of the paper dealt with the theory of the effects of lightning strokes on overhead transmission lines. It is concluded that direct strokes to overhead conductors are certain to cause flash-over; but interruption of the supply may be minimized either by fitting devices, such as special choke coils or protective gaps, or by the installation of overhead earth wires, which will prevent any strokes falling on the line conductors. Emphasis was laid in the paper on the fact that in order to protect an insulated line from flash-over, when either a tower or the earth wire is struck it is necessary to ensure that the effective resistance of the earth connexion of the tower is reduced to a low value For example, it is deduced that no flash-over will occur on a line insulated with chains of nine standard cap-and-pin units, if the tower footing resistances are less than 10 ohms. It may not, however, always be possible to secure a sufficiently low value of this resistance to avoid flash-over.

Observation of Orionids, Leonids and Geminids in 1936

KÔZIRÔ KOMAKI, of Kanaya, Aritagun, Wakayama-ken, Japan, has sent the results of his observations of these three showers. The Orionids were very numerous, and he states that he has not observed such a rich display for ten years. On the night of October 21 the rate was more than 33 an hour—a very high rate for this shower. The eastward shift in the radiant from night to night was very obvious. Thus on October $20{\cdot}72^{\mathrm{d}}$ U.T. the position of the radiant was 93·5°+13°, and on October $27{\cdot}77^{\mathrm{d}}$ it was 99·5°+6·5°. A number of other observers in different parts of Japan obtained results similar to those of Mr. Komaki. Mr. K. Yasii at Takehara attempted to photograph meteors during the period of the Orionids, and succeeded in obtaining 10, of which 4 were Orionids. On November 12–16 watch was kept for the Leonids, but the apparition was very poor, only 5 being observed hourly on November 17, when the maximum was attained. Several Andromedids were observed on November 21 by Mr. Sanekata, but nothing is said about the radiant. The Geminids were seen on December 10–16, the maximum being attained on December 13–14, when the frequency was about 40 hourly. This is similar to the rate in previous years. The radiant showed the eastward movement usually observed with this shower. On December $12{\cdot}76^{\mathrm{d}}$ U.T. it was at 113°+32·5° and on December $15{\cdot}65^{\mathrm{d}}$ at 115°+32·5°.

American Association for the Advancement of Science

ATLANTIC CITY MEETING

THE ninety-ninth meeting of the Association was held in Atlantic City, N.J., on December 28–January 2, where one meeting had been held previously, namely, in 1932. This was to many of the members a strange setting for a great scientific assembly with the wide board-walk winding along close by the breakers of the Atlantic, and lined on the other side by shops in endless variety over which tower the great hotels, the comforts and service of which have made Atlantic City famous. One found no great university buildings, no richly stored museums, no famous research laboratories such as usually shelter the sessions and stimulate the activities of Association meetings. But all pronounced the meeting a success; the weather was mild, the sea beautiful, the attendance good, and the facilities adequate to serve well all needs of the occasion.

The splendid Municipal Auditorium, with numerous audience rooms of varied capacity, and the well-planned meeting-places in the big hotels brought closer together than ever before the sessions of the fifteen sections and some forty associated societies and conferences included in the programme. Time spent in reaching distant meetings was saved, conferences were easily arranged, and personal contacts more frequent. Important as are the formal papers, one must rate of even higher value the discussions between and after meetings when new ideas are subjected to the keenest criticism. All conditions at Atlantic City contributed to further interchange of views and to strengthen the unity of the Association

The opening general session on December 28 was devoted primarily to the address of the retiring president, Dr. Karl T. Compton, on "The Electron: Its Intellectual and Social Significance". Dr. Compton used the discovery of the electron, which apparently had no practical use when first found and measured, as the example of how pure research turns into valuable practical application. He enumerated industries made possible by electronic devices which have a total business of hundreds of millions of dollars each year, and added that the application of the discovery of the electron has brought intangible values in improved health, safety and convenience. Taking a swift audit of the electron's money contribution to civilization, Dr. Compton pointed out that it is responsible for a growing industry in electronic devices which now amounts to a total business of 50,000,000 dollars a year in America alone.

The Sigma Xi address on December 29 was given by Dr. Henry G. Knight, chief of the U.S. Bureau of Chemistry and Soils, on "Selenium and Its Relation to Soil, Plants, Animals, and Public Health". The Phi Beta Kappa address on December 30 was delivered by President James R. Angell, of Yale University; his subject was "The Scholar and the Specialist".

Special afternoon general lectures were given on December 28 by Dr. E. O. Hulbert, of the Naval Research Laboratory, on "The Optics of the Surface of the Sea", on December 29 by Mr. David Dietz, science editor of the Scripps-Howard newspapers, on "Science and the American Press", and on December 30 by Dr. P. W. Zimmerman, of the Boyce Thompson Institute for Plant Research, on "Response of Plants to Hormone-like Growth Substances". The last mentioned item was a formal presentation before the Association of the subject awarded the Association Prize at St. Louis last year.

The Section on Medical Sciences devoted four days to a continuing symposium on cancer, covering in series of invited papers by leaders in cancer research the position of various aspects of present-day investigation. The morning of December 29 was devoted to various types of radiation and their effects, and the afternoon to heredity and constitutional factors; the following morning and afternoon to induction, stimulation and inhibition of tumorous growths; and the morning of December 31 to the metabolism of cancerous tissue. On the afternoon of December 30, Dr. C. C. Little, director of the Jackson Memorial Laboratory, gave the afternoon general lecture on the subject "The Social Significance of Cancer". A general lecture was given on January 1 by Dr. Walter Schiller, of the University of Vienna, on "Changes and Modifications in the Conception of Carcinoma". All told, this series constituted the most complete presentation of the cancer problem and the results of research in this field yet organized in the United States. The sessions were largely attended and the discussions prolonged.

Some new features were introduced into the programme at Atlantic City. Friday, January 1, was designated Association Day and devoted to general purposes. The morning was utilized for meetings of sectional committees, scientific boards and the Secretaries' Conference of the Association. In the afternoon was held a demonstration symposium on "The Moving Picture in the Service of Science". In one large auditorium Dr. William Beebe showed his reels on "Bathosphere Embryonic Eels", made under the auspices of the New York Zoological Society. Following this, Mr. Perry Burgess, president of the Leonard Wood Memorial, presented a sound movie of dramatic interest, "Miracles in the South Sea", portraying life in the leper colony in Culion, P.I. At the same time in a separate auditorium Prof. E. M. K. Geiling, of the University of Chicago, and Mr. L. L. Robbins illustrated "Whaling for Science" in a film showing habits of the cetacean and search for the hypophysis. "High Speed Motion Pictures of the Flight of Birds and of Bullets", a series of great interest, was shown by Dr. H. E. Edgerton, of the Massachusetts Institute of Technology. A colour film entitled "A Health Educator with a Cine-Kodak in the Orient" was exhibited and described by Dr. C. E. Turner, of the Massachusetts Institute of Technology; he presented vividly the mode of life, problems of population and sanitation in those regions.

The closing event in Atlantic City was a special showing on Friday evening (January 1) of "The Human Adventure", an eight-reel talking picture sketching man's rise from savagery to civilization. The late Dr. James Henry Breasted, director of the Oriental Institute at the University of Chicago, had supervised personally the production of this film and the sound record was partly in his own voice.

On January 2 the Association moved to Philadelphia on invitation of the American Philosophical Society, and in its famous hall heard a programme on viruses and virus diseases. The first paper, by Dr. W. M. Stanley, included a survey of the work granted the Association Prize. After the luncheon, visiting members were taken to the Franklin Institute and the Academy of Natural Sciences, where scientific programmes had been arranged.

The newly elected president of the Association, Dr. George D. Birkhoff, recently made Dean of the Graduate School of Arts and Sciences at Harvard, where he has been professor of mathematics since 1919, presented before the mathematicians an important paper entitled "A Conceptual Theory of Atomic Structure". This paper, which gives physicists a clearer comprehension of the composition of matter, presents anew to modern thought fundamental ideas first advanced by the illustrious James Clerk Maxwell. It is interesting to recall that in 1926 Dr. Birkhoff was awarded the Association Prize of the Philadelphia meeting for his paper demonstrating that Schrödinger's fundamental wave equation, then recently published, could be reached on the basis of a conceptual theory of matter and electricity.

The Association prize for an outstanding contribution to science in the Atlantic City programme was given to Dr. W. M. Stanley, of the Rockefeller Institute for Medical Research, for his paper entitled "Crystalline Tobacco-Mosaic Virus Protein". After reporting his experiments and analysing their significance with thoroughness, he concluded his paper as follows:

"In view of the properties which this protein possesses, the borderline between the living and the non-living tends to become non-existent, for, although it possesses properties which have been regarded as characteristic of living things, such as specificity of host range and the ability to reproduce and to mutate, it is nevertheless a protein molecule and as such may be regarded as non-living. It is possible that by virtue of its size, it is enabled to possess sufficient organization within the molecule to endow it with such properties. As such, it would represent a link between the type of organization within the atom or molecule with which chemists have concerned themselves and the type of organization within the cell with which biologists have been concerned."

The attendance at Atlantic City was large, being variously estimated from four to five thousand, of which 2,400 were officially registered. At the various sessions fourteen hundred papers were presented. Despite the variety of these offerings, the audience rooms were filled to capacity. The scientific exhibition was especially well visited and its numerous exhibits attracted favourable comment. Special mention may be made the remarkable research exhibit of Dr. Irving Langmuir, the Nobel laureate in chemistry, who has produced the world's thinnest films.

The addresses of the retiring vice-presidents, given at various times, included the following:

Mathematics: Prof. T. H. Hildebrandt, of the University of Michigan, on "Recent Developments in the Theory of Integration"; *Physics:* Prof. John T. Tate, of the University of Minnesota, on "Electron Impacts in Gases"; *Chemistry:* Prof. Moses Bomberg, of the University of Michigan, on "Free Radicals"; *Astronomy:* Dr. H. R. Morgan, of the United States Naval Observatory, on "Some Problems in Fundamental Astronomy"; *Zoology:* Dr. Ross G. Harrison, of Yale University, on "Embryology and Its Relations"; *Botany:* Prof. E. W. Sinnott, of Columbia University, on "Morphology as a Dynamic Science"; *Anthropology:* N. C. Nelson, of the American Museum of Natural History, on "Prehistoric Archæology, Past, Present, and Future"; *Psychology:* Dr. Robert M. Ogden, of Cornell University, on "The Psychology of Art: Naive Geometry"; *Education:* Prof. F. B. Knight, of the University of Iowa, on "Data Related to Classroom Learning"; *Social and Economic Sciences:* Dr. Shelby Harrison, of the Russell Sage Foundation, on "Winning Social Advance Through the Process of Accretion"; *Historical and Philological Sciences:* Dr. George Sarton, of Harvard University, on "The Study of the History of 20th Century Science"; *Agriculture:* Prof. H. K. Hayes, of the University of Minnesota, on "Agricultural Research in China".

The following officers were elected for the terms indicated in parenthesis:

President (1937): George D. Birkhoff, of Harvard University;

Permanent Secretary (1937–40): Forrest R. Moulton, formerly professor of astronomy, University of Chicago;

General Secretary (1937–40): Otis W. Caldwell, of Boyce Thompson Institute for Plant Research;

Treasurer (1937–40): John L. Wirt;

Elected Council Members (1937–40): Vincent du Vigneaud, of George Washington University Medical School, and Sam F. Trelease, of Columbia University;

Members of the Executive Committee (1937–40): Edwin G. Conklin, of Princeton University, and Henry B. Ward, professor emeritus of the University of Illinois;

Member of the Board of Trustees of Science Service (1937–39): J. McKeen Cattell, editor of *Science;*

Members of the Finance Committee (1937–40): Arthur Keith, of the United States Geological Survey, and (1937–38) Charles S. Baker, Munsey Building, Washington, D.C.;

Members of the Committee on Grants (1937–40): A. T. Poffenberger, of Columbia University, and Jacob G. Lipman, of the New Jersey Agricultural Experiment Station;

Vice-Presidents of the Sections (1937):

W. D. Cairns, Oberlin College (Mathematics);
Harvey Fletcher, the Bell Telephone Laboratories (Physics);
Farrington Daniels, the University of Wisconsin (Chemistry);
Philip Fox, the Adler Planetarium and Astronomical Museum (Astronomy);
Kirtley F. Mather, Harvard University (Geology and Geography);
Ralph S. Lillie, the University of Chicago (Zoological Sciences);
F. E. Denny, the Boyce Thompson Institute for Plant Research (Botanical Sciences);
John R. Swanton, the United States Bureau of American Ethnology (Anthropology);
A. T. Poffenberger, Columbia University (Psychology);
Stuart Rice, United States Central Statistical Board (Social and Economic Sciences);
R. C. Archibald, Brown University (Historical and Philological Sciences);

J. W. Barker, Columbia University (Engineering);
Esmond R. Long, the University of Pennsylvania (Medical Sciences);
E. C. Auchter, the United States Bureau of Plant Industry (Agriculture);
Ralph Tyler, Ohio State University (Education).

Secretaries of the Sections (1937–40):
E. R. Hedrick, the University of California at Los Angeles (Mathematics);
H. A. Barton, the American Institute of Physics (Physics);
Neil E. Gordon, of Johns Hopkins University (Chemistry).
Harlan T. Stetson, the Massachusetts Institute of Technology (Astronomy);
Howard Meyerhoff, Smith College (Geology and Geography);
George A. Baitsell, Yale University (Zoological Sciences);
J. T. Buchholz, the University of Illinois (Botanical Sciences);
W. M. Krogman, Western Reserve University (Anthropology);
Leonard Carmichael, the University of Rochester (Psychology);
E. P. Hutchinson, 11 Centre Street, Cambridge, Mass. (Social and Economic Sciences);
Joseph Mayer, Library of Congress (Historical and Philological Sciences);
F. M. Feiker, the American Engineering Council (Engineering);
Malcolm Soule, the University of Michigan (Medical Sciences);
M. F. Morgan, the Connecticut Agricultural Experiment Station (Agriculture);
P. M. Symonds, Columbia University Teachers College (Education).

HENRY B. WARD.

The Wellcome Trust

SIR HENRY WELLCOME, who died on July 25, 1936, at the age of eighty-two years, was known as the creator of a great manufacturing business and also for the active interest he took in archæological and geographical exploration, the social welfare of native races and the promotion of fundamental research in sciences on which the progress of medicine depends. Beginning so long ago as 1894, he founded in that year the Wellcome Physiological Research Laboratories, and two years later a corresponding centre for chemical research. In 1899, he established the Wellcome Tropical Research Laboratories at Khartoum, where the late Sir Andrew Balfour worked as director for twelve years, doing notable work on the control of malaria and the investigation of other tropical diseases. In 1913 the Wellcome Bureau of Scientific Research was brought into being to control the various research laboratories already operating, and then followed the Historical Medical Museum, the Museum of Medical Science and the Entomological Field Laboratory. All these institutions, with the exception of the physiological and entomological laboratories, are now housed in the magnificent Wellcome Research Institution in Euston Road, London. This was Sir Henry's crowning gift; the corner-stone was laid in 1931 by the late Lord Moynihan, who said that the ceremony might well be regarded as referring to the corner-stone of a long life's work.

By his will, Sir Henry provided for the continuance of the Wellcome Research Institution, the trustees appointed to administer the estate being Sir Henry Dale, F.R.S., director of the National Institute for Medical Research; Prof. T. R. Elliott, C.B.E., F.R.S., professor of medicine in the University of London; Messrs. G. Hudson Lyall and L. C. Bullock, members of a London firm of solicitors; and Mr. Martin Price, chartered accountant.

The accompanying statement has now been issued by the five trustees:

As the trustees appointed by the will of the late Sir Henry Wellcome, we ask you to be good enough to publish this letter in order to clear up any misconception which may have arisen with regard to the effects of the will. We are led to make this statement by the number of appeals for contributions to various research undertakings which have already reached us. For reasons mentioned below the trustees will not be able to consider any such applications in the immediate future.

In January 1924 the Wellcome Foundation Limited was formed for the purpose of taking over the whole of the business activities of Burroughs Wellcome and Co., and the various scientific research institutions and museums established by the late Sir Henry Wellcome, who held the whole of the share capital.

By the terms of the will the shares of the Wellcome Foundation are now vested in us as trustees, and the activities of the Foundation throughout the world will be carried on, in collaboration with the trustees, by a Board of Directors of which the present Governing Director is Mr. George E. Pearson, who has been closely associated with the late Sir Henry Wellcome for more than forty years.

It will be realized that owing to the magnitude of the testator's estate, a very large sum has to be found for death duties. Provision has also to be made for:

(*a*) A welfare fund for the benefit of employees of the Wellcome Foundation Ltd., and its associated companies.

(*b*) The payment of certain specified annuities to relatives and others personally connected with the testator.

(*c*) The erection and maintenance of a building in Minnesota to be dedicated as a memorial to the testator's parents.

Subject to these prior charges, the remainder of the divisible profits will be utilized in accordance with the testator's instructions in the following manner:

(i) For the maintenance of "The Research Undertaking Charity", which is a fund for the advancement of medical and scientific research work in any part of the world conducive to the improvement of the physical conditions of mankind, and in particular for the discovery, invention and improvement of medicinal agents and methods for the prevention and cure of disorders, and the control or extermination of insect and other pests which afflict human beings and animal and plant life, and also for the organization, equipment and expenses of special research expeditions and commissions.

(ii) For the maintenance of "The Museum and Library Charity", which is a fund for the establishment or endowment of research museums or libraries in any part of the world and for the collection of information of every kind connected with the history of medicine, surgery, chemistry, bacteriology, pharmacy and allied sciences, which in the opinion of the trustees may be desirable.

This statement of the position has been somewhat delayed by the fact that the testator imposed upon all his trustees the obligation, before undertaking the trust, to enter into a covenant not to be engaged in or in any way to assist in any concern which carried on a business in competition with Burroughs Wellcome and Co. Three of the trustees had no difficulty in entering into this covenant immediately after the testator's death, but the two medical and scientific trustees felt that certain words in the covenant might be held to restrict them unduly in the performance of their official and general duties to medical science, and to imply their particular concern with the business interests of the Foundation. The matter has now been considered by the High Court of Justice, which has made an order allowing them to enter into a covenant in a form removing any such unacceptable implication and enabling effect to be given to what was known to have been the testator's intention.

No trustee, director, or any other person holds for himself or in his own right any shares in the Wellcome Foundation, and all the divisible profits in each year will be devoted to the various purposes named in the will and indicated above.

We believe this to be the first example, in Great Britain at least, of a testamentary disposition by which the whole of the profits from a great manufacturing and trading organization, after certain personal and memorial bequests have been fulfilled, are permanently dedicated to the advancement of knowledge for the general benefit of mankind.

G. HUDSON LYALL,
H. H. DALE,
L. C. BULLOCK,
MARTIN PRICE,
T. R. ELLIOTT.

The proviso which, by order of the Court, may be added by a trustee to the covenant required of all the trustees under the will of Sir Henry Wellcome, reads as follows:

"PROVIDED that nothing in this Covenant shall be held to prevent me in the exercise of my proper function in any appointment held by me in the public service or under any publicly or privately endowed organisation for the promotion of medical research or under any University in Great Britain from giving advice on scientific matters to any person or persons solely for the purpose of rendering scientific discovery available for the general use and without pecuniary reward or other personal advantage to myself."

Prize Awards for 1936 of the Paris Academy of Sciences*

THE LOUTREUIL FOUNDATION

Researches on Fixed Problems.—Pierre Auger (3,000 francs), for his researches on cosmic physics requiring a stay at the Jungfraujoch Laboratory; Abel Brion (3,000 francs), for his researches on the pathological physiology of the kidney in animals; Raymond Cahen (2,000 francs), for his researches on tolerance to morphine in the rat and rabbit; Claude Charmetant (3,000 francs), for his researches on the electrolysis of chlorides, bromides and iodides in aqueous alcoholic solutions; H. Girard (1,000 francs), for the study of blood groups and the transfusion of blood in animals; Henri Laugier (3,000 francs), for his researches on circulation reactions during emotion; Gustave Lesbouyries and Maurice Berthelon (2,000 francs), for their researches on the genital hormones of animals; Paul Marsais (2,000 francs), for the continuation of his studies on the diseases of the vine, especially mildew and its treatment; Louis Nattan-Larrier (6,000 francs), for helping him continue his work on the serological condition of the development of normal tissues and cancers; Paul Nottin (3,000 francs), for his researches on the action of the impurities of sulphuric acid due to the Glover tower on alcoholic fermentation; the Besançon Observatory (5,000 francs), for the organization of a French office of isostatic reduction; Maurice Pierre (3,000 francs), for the study of Hering's nerve in domestic animals; Antoine Poidebard (5,000 francs), for his researches on submarine photography at Tyre; Emile Roubaud (5,000 francs), for his researches on the locust; Henri Simonnet (2,000 francs), for his chemical and physiological researches on the fate of morphine in the animal organism; Charles Alluaud (4,000 francs), for his zoological researches in the Sahara; Jean Gruvel (5,000 francs), as a contribution to an expedition to Indo-China for the study of the ichthyological fauna.

Purchase of Laboratory Material.—Emile André (3,000 francs), for the purchase of a polarimeter for the determination of rotatory power as a function of the wave-length; Henri Lafuma (3,500 francs), for the purchase of a testing machine for refractory products; Marcel Véron (3,500 francs), for the purchase of a spectrobolometer.

Publications.—Comité de Physique du Globe des Colonies (8,000 francs), for the publication of the "Annales de Physique du Globe de la France d'outre-mer"; Fédération française des Sociétés de Sciences naturelles (5,000 francs), for the publication of the "Faune de France"; André Guillaumin, for assisting in the publication of a new guide to the collection of living plants in the Jardin des plantes; Louise Nouvel (3,000 francs), for the publication of a work on the biology of the Natantia crustaceans.

Grants to Libraries.—Ecole nationale vétérinaire d'Alfort (5,000 francs), for preparing a card index and completing its foreign periodicals; Ecole national vétérinaire de Toulouse (6,000 francs), for completing its collections; Ecole polytechnique (6,000 francs), for the purchase of scientific publications; Institut national agronomique (6,000 francs), for the completion of its collection of foreign periodicals.

---

* *Continued from p. 162.*

MME. VICTOR-NOURY FOUNDATION

René Bourret (2,500 francs), for his work on the snakes of Indo-China; Elisabeth Jérémine (2,500 francs), for researches in petrography; Robert Didier and Paul Rode (2,000 francs), for their work on the mammals of France; Jules Guart (2,000 francs), for his book on the parasitic cestodes obtained during the voyages of Prince Albert of Monaco, 1886-1913; Jacques Pochon (2,000 francs), for his work on the role of a cellulolytic bacterium of the paunch in the digestion of cellulose in ruminants; Henri Stehlé (2,000 francs), for starting his work on the flora of Guadeloupe; André Thomas (2,000 francs), for work in experimental cytology; Voldemar Vilter (2,000 francs), for his work on the formation of the feather and its histological mechanism; Elisabeth Sylvain-David (2,000 francs), for the publication of a memoir on the Foraminifera.

GENERAL FOUNDATIONS

The Pierre Lafitte Foundation to Robert Bureau, for his researches on the origin of atmospherics in wireless telegraphy and on the use of electro-magnetic waves for recording observations made in captive balloons; the Millet-Ronssin Foundation between René Herpin (4,000 francs), for fitting up his laboratory of marine zoology, Fernand Obaton (3,000 francs), for his cinematographic studies of the movements of plants and the organization of a research centre of this nature at the Sorbonne, and Nicholas Théobald (3,000 francs), for his work on fossil insects.

THE VILLEMOT FOUNDATION

Aimé Cotton (40,000 francs), for his researches at Bellevue with the large electro-magnet of the Academy; Pierre Augustin Dangeard (10,000 francs), for his botanical studies; Roger Heim (12,000 francs), for the study of the cryptogam material collected by him in Madagascar and the publication of the results; Gaston Julia (5,000 francs), for the mathematical circle which meets at the Henri Poincaré Institute for the study of current mathematical questions; Laboratoire central d'électricité (10,000 francs), for the purchase of apparatus for researches on the determination of the ohm in absolute measure with high precision; Raoul Lecoq (10,000 francs), for his work on the study of vitamins in unbalanced food regimes; Père Lejay (10,000 francs), for work on solar phenomena at the Zi-Ka-Wei Observatory; Pierre Lesage (6,000 francs), for his researches on heredity in plants of the acquired physiological character, precocity; Berbard Lyot (30,000 francs), for his studies on the solar corona; Charles Mauguin (20,000 francs), for acquiring apparatus designed for the analysis of the crystalline structures of minerals; Jean Piveteau (10,000 francs), for resuming excavations in the celebrated Perrier deposit of Tertiary mammals; Hyacinthe Vincent (12,000 francs), for work relating to the etiology and pathogeny of certain infectious diseases.

The Charles Frémont Foundation to Jean Feytaud, for his researches on noxious insects and the organization of defensive measures against these enemies.

SPECIAL FOUNDATIONS

The Lannelongue Foundation to Mme. Gabriel Cusco; the Hélène Helbronner-Fould Prize to Mme. Marie Phisalix, for her work on snake poisons; the Girbal-Baral Foundation to Mlle. Yvette Cauchois (10,000 francs), for her studies on the spectrography of the X-rays, and Roger Gautheret 10,000 francs), for his studies on the culture of plant tissues.

Air Resistance of Passenger Trains

IN a paper read before the Institution of Mechanical Engineers on November 27, Mr. F. C. Johansen describes the results of experiments on the air resistance of passenger trains produced by modifying the shape and the smoothness of their surfaces, originally of L.M.S. pattern, in two different ways. In the first way, there was no general change in the external form of the coaches, but in the second way all coaches have smoothed bodies and faired under-carriages. The modifications introduced involved no marked alteration from the conventional appearance except for fairings on the engine, tender and the tail end of the last coach, the object being to show what reductions in air resistance could be achieved without any radical degree of stream-lining.

In the first way, the reduction of the longitudinal force was of the order of 20 per cent and decreases with the increase of the length of the train, since the reduction is mainly due to the locomotive and the first coach. In the second way, the reduction of the longitudinal force was much larger, being of the order of 50 per cent, the more effective lining being due to the all-smooth coaches. In the ideal train the corresponding reduction of the force would be about 75 per cent. The experimental results lead to the following recommendations and conclusions.

The air resistance of a train of conventional British type is equivalent to about 0·0016 V^2 lb. per ton of train weight, where V is the speed in still air in miles per hour. The air resistance can be reduced by 50 per cent without drastic departure from conventional design and by 75 per cent by ideal stream-lining With speeds of 100 m.p.h., the corresponding fuel economy would be about £1 per hour.

It was found that the air resistance was augmented by side winds, this effect being mainly due to frontal pressure on exposed surfaces. Curiously enough, the worst natural wind is not directly ahead but ranges from 30° to 60° on either side of this direction. Stream-lining measures are more effective in side winds than in direct winds. The gaps between the coach bodies of an ordinary train account for very little of the total air resistance. A surprisingly large proportion of the air resistance of a coach is contributed by the bogies and under-carriage structure. A fair shape at the tail end of a train reduces air resistance to an extent which is more marked the more complete the stream-lining.

The full benefit of measures to reduce air resistance can be realized only if the locomotive and the coaches are all stream-lined. The final conclusion the author arrives at is that the ideal stream-lined train is a continuous cylindrical body with well-rounded ends, having a polished surface free from external fittings and irregularities. A tubular surface, incorporating a stressed skin of sheet metal, would be very suitable.

Science News a Century Ago

The Polarization of Heat

WHEN Whewell was publishing his "History of the Inductive Sciences", Forbes wrote to him on January 31, 1837: "I feel gratified by the prominent place you have given to my experiments as bearing upon the theory of Heat. . . . But I must mention for yourself, if not for your book, that the discovery of the polarization of heat was not the necessary consequence of applying the thermo-multiplier to the investigation, which would have been a poor achievement, seeing it was another man's invention; but that Melloni had first applied the instrument to the tourmaline question, and answered in the negative (*Ann. de Chemie*, vol. 55); then Nobili, the inventor, attempted to repeat Berard's experiment with the most approved piles, and with results quite null (*Bib. Universelle*). So that I conclude that, when I published my experiments, the question of polarization was negatively answered by persons operating with every advantage which I possessed, and indeed seemed to be set at rest. My discovery was the application of mica as a polarizing substance, first by transmission, then by reflection; and I have shown that repeating Nobili's experiment—the same as Berard's and Powell's—the quantity of heat reflected from glass is so excessively minute that the errors might well equal the total effect. I think you have not mentioned total reflection and circular polarization.

"As to simple reflection, Melloni should be mentioned alone, but I claim double refraction."

The Zoological Society

AT a meeting of the Zoological Society held on February 2, 1837, the Rev. John Barlow being in the chair, it was stated that the receipts for the preceding month had been £2,146 12*s*. 2*d*. and the expenditure £1,019 6*s*. 3*d*. The number of visitors to the menagerie was 1,666, from whom £42 14*s*. was received, and the number of visitors to the museum 219, from whom £4 1*s*. was received. It was also stated that Mr. Yarrell had agreed to act as secretary without emolument, provided an assistant secretary was appointed, which the council had taken steps to do. The number of mammalia in the menagerie was 294, the number of birds 693 and the number of reptiles 27.

Dr. John Latham (1740-1837)

DR. JOHN LATHAM, an eminent ornithologist and archæologist, and one of the many celebrated truants of medicine, who died on February 4, 1837, was born in 1740 at Eltham in Kent, the son of a surgeon. He was educated at Merchant Taylors School and studied medicine under John Hunter. He practised for many years at Dartford, where he acquired a considerable fortune which enabled him to retire in 1796 to Romsey and devote all his energies to the study of archæology and ornithology. He was elected F.S.A. on December 15, 1774, and F.R.S. on May 25, 1775, and took a leading part in the foundation of the Linnean Society in 1788. He was the author of a "Synopsis of Birds" published in 1785, to which he added supplements in 1787 and 1802, and in 1790 brought out an abstract of this work entitled "Index Ornithologicus". Owing to financial losses, he was compelled to sell a great part of his library and museum, but with a rare courage, at the age of eighty-one years, he attempted to restore his fortune by an enlarged edition of his "Synopsis" entitled "A General History of Birds" which appeared between 1821 and 1828 in eleven volumes at Winchester, to which he had moved in 1820. He also took part in the revision of the second edition of Pennant's "Indian Zoology" published in 1793, and contributed several papers to the *Philosophical Transactions*, *Transactions of the Linnean Society* and *Archæologia*.

The subject of this note must not be confused, as was done in his obituary notice in the *Gentleman's Magazine* of July 1837, with another Dr. John Latham, Harveian orator in 1794 and president of the Royal College of Physicians in 1813–20.

Baron Desgenettes (1762-1837)

FEBRUARY 3 marks the centenary of the death of one of the most eminent medical men in Napoleon's army, Baron Réné Nicolas Dufriche Desgenettes. He was born at Alençon on February 23, 1762, and after studying medicine at Montpellier and Paris, he qualified at Montpellier in 1789 with a Latin thesis on the lymphatics. The next two years he spent at Montpellier, and then returned to Paris, where he enjoyed the society of some of the most illustrious savants of the time, such as Pelletan, Tenon, Sabatier, Condorcet, Vicq D'Azyr and Louis. On the advice of the last two, he joined the army, where in 1794 he first made the acquaintance of Napoleon. Two years later he was appointed physician and lecturer to the recently established Val-de-Grâce Military Hospital and Medical School, where he published several works on education and the treatment of war diseases, and took an active part in the foundation of two medical societies.

The next step in Desgenettes' career was his appointment by Napoleon as principal medical officer in the Egyptian and Syrian campaigns, in which he distinguished himself by his heroism and devotion to the sick and wounded. In 1802 he was made head of the Val-de-Grâce Hospital and shortly afterwards Inspector General of the Health Service of the French army. In 1805 he was sent to Spain to study the epidemic which was ravaging Cadiz, Malaga and Alicante. After taking part in the campaign in Prussia and Poland, he was made prisoner by the Russians, but was released by the Czar in gratitude for his care of the Russian wounded. At the battle of Waterloo he served as chief medical officer of the army and of the Imperial Guard. In 1822, owing to the sweeping changes made by the Frassinous régime, he was ousted from the chair of hygiene to which he had been appointed by the Directory, but was restored to it in 1830.

Desgenettes belonged to several learned societies, including the Paris Academy of Sciences, and was one of the first members of the Paris Academy of Medicine founded in 1820. He was a copious writer, his chief works being "Notes on the History of the Army in Italy" (1797), "The Medical History of the Army in the East (1802) and "Essays on Medical Biography and Bibliography" (1825).

University Events

CAMBRIDGE.—At Queens' College, Dr. G. P. McCullagh has been elected to a reserved fellowship. Dr. McCullagh is a former scholar of the Queen's University, Belfast, where he took his M.D. in 1931 and was Riddel demonstrator in pathology from 1932 until 1935. In 1935 he was appointed a University demonstrator in pathology at Cambridge.

GLASGOW.—The curators of patronage have appointed Dr. John W. S. Blacklock, lecturer on the pathology of diseases of infancy and childhood at the Royal Hospital for Sick Children, to the St. Mungo (Notman) chair of pathology at the Royal Infirmary. Prof. Blacklock will be, *ex officio*, pathologist to the Royal Infirmary.

A gift of £10,000 has been promised by Imperial Chemical Industries, Ltd., towards the cost of erecting the new Chemistry Institute at Gilmorehill. The cost is estimated at £200,000, and £118,000 has been assured by the Carnegie Trustees for the Scottish Universities.

Prof. E. B. Bailey has resigned from the chair of geology on his appointment to the directorship of the Geological Survey. His resignation will take effect from March 31, 1937.

LONDON.—The title of professor of geology (oil technology) in the University has been conferred on Mr. V. C. Illing, in respect of the post held by him at the Imperial College—Royal School of Mines; that of reader in physiology in the University on Dr. W. H. Newton, in respect of the post held by him at University College, and that of emeritus professor of education in the University on Sir T. Percy Nunn, on his retirement from the University professorship of education at the Institute of Education.

The degree of D.Sc. in horticulture has been conferred on Mr. H. V. Taylor, of the Imperial College—Royal College of Science; and that of D.Sc. in hygiene on Mr. Thomas Bedford, an external student.

OXFORD.—In Convocation on January 21 the honorary degree of D.Sc. was conferred on Dr. John D. Pollock, chairman of Metal Industries Limited, and of the British Oxygen Company, a Carnegie Trustee and benefactor to the Engineering and Physics Departments of the University.

Societies and Academies

Paris

Academy of Sciences, January 4 (*C.R.*, 204, 1–76).

LÉON LECORNU: The suppression of friction.

CHARLES ACHARD and MAURICE PIETTRE: Researches on the blood serum and muscular plasma in the fœtus.

LOUIS LÉGER and MLLE. MARCELLE GAUTHIER: *Graminella bulbosa*, a new genus of parasite entophyte of the larvæ of Ephemerids of genus *Bætis*.

CARLOS BIGGERI: The singularities of analytical functions defined by potential series.

GEORGES VALIRON: The variations of the modulus of integral or meromorph functions.

JEAN ROUBAUD-VALETTE: The use of hypercomplex numbers for establishing the equations of a relativist wave mechanics.

C. DAUZÈRE: The electrical conductivity of the air in a potash mine in Catalonia. From the experiments described it would not appear that potassium has any marked effect in increasing the ionization of the air above granite rocks.

FÉLIX EHRENHAFT: An experimental method for finding the errors of determination of the size of an object by the microscope.

RENÉ FREYMANN: The absorption spectra in the near infra-red of solutions of alcohols in ether or dioxan: oxonium formation. The disappearance of the (OH) band from the infra-red spectrum of alcohols in certain solvents (ether, dioxan, acetone) is interpreted as being due to the formation of an oxonium compound.

WILFRIED HELLER: An attempt at a classification of syneresis.

MLLE. SUZANNE ESTRADÈRE: Relations between indices of shock, cracking, the oxidation of hydrocarbons and its thermal effects.

ALBERT PORTEVIN and DIRAN SÉFÉRIAN: The influence of elements added to steel on the nitrogen absorption on fusion in the arc. The addition of carbon, manganese and silicon tends to reduce the absorption of nitrogen: special elements (except titanium) increase the absorption.

HENRI MOUREU and GEORGES WETROFF: The existence and the stability of the phosphonitril radical, PN, and the synthesis of phosphorus dichloronitride. Attention is directed to the analogy between the groups CN and PN. The paranitride $(PN)_n$, treated at about 500° C. with chlorine, does not give nitrogen and PCl_5 as might be expected, but an addition compound, $(PNCl_2)_3$.

GUSTAVE VAVON and ISRAËL CHILOUET: The bornylamines.

HENRI LONGCHAMBON: The characteristics of the palygorskites. The examination of a considerable number of specimens proves the close analogy between palygorskites and sepiolites, and confirms the hypothesis of Fersmann, that palygorskites are derived from sepiolites by the isomorphic replacement of magnesium by aluminium.

GILBERT MATHIEU: The two large tectonic units of Vendée.

HENRI V. VALLOIS: The duration of life in fossil man. The character utilized for the determination of the age was the synosteosis of the cranial sutures. Out of 173 subjects, only three appear to have survived more than fifty years. It is probable that in Palæolithic and Mesolithic times death coincided with the decline of the physical powers.

ROBERT KÜHNER: The nuclei and their divisions in the carpophore, especially in *Mycena*.

PIERRE P. GRASSÉ: Hemaphrorrhea, reflex reject of blood and air by the phymateid Acridians. When *Dictyophorus oberthuri* is handled, bubbles of froth appear at various points of the body, and this froth was found to be composed of blood and air.

GEORGES TEISSIER: The biometrical comparison of two species of the genus *Maia*.

JEAN ROCHE and RENÉ COMBETTE: The physical state of globin and molecular weight of the methæmoglobin obtained by the combination of protohæmatin with globin.

MLLE. CAMILLE CHATAGNON: The urinary elimination of bromine after ingestion of sodium bromide.

Yves Raoul: A new synthesis of hordenine. Tyramine is prepared by heating tyrosine under reduced pressure at 250° C., and this is methylated by means of formaldehyde in the presence of formic acid. At the boiling point, a 50 per cent yield of hordenine is obtained: at the ordinary temperature after a month, a 16 per cent yield is obtained.

Amsterdam

Royal Academy (Proc., 39, No. 10, Dec. 1936).

A. Kappers: The spread of primitive humanity and its links with the more differentiated races, as revealed by cephalic and cranial index curves.

L. S. Ornstein: Scattering of neutrons in matter (4).

J. Clay and H. F. Jongen: The absolute intensity of cosmic radiation at sea-level.

E. Cohen and A. K. W. A. van Lieshout: The influence of mechanical deformation on the velocity of transformation of polymorphous metals (3). The influence of metallic admixtures (2).

E. Dubois: Racial identity of *Homo soloensis* Oppenoorth (including *Homo modjokertensis* von Kœnigswald) and *Sinanthropus pekinensis* Davidson Black.

H. Brinkman: A continuously acting cloud-chamber.

E. Gorter, L. Maaskant and G. J. van Lookeren Campagne: The spreading of fibrinogen.

I. Lifschitz: Dissymmetrical synthesis in the case of complex metallic salts (2).

J. Westerveld: The granites of the Malayan tin-belt compared with tin-granites from other regions.

S. T. Bok: The branching of dendrites in the cerebral cortex.

T. Reichstein, E. Laqueur, I. E. Uyldert, P. de Fremery and R. W. Spanhoff: An active crystalline substance from the cortex of the suprarenal gland—corticosterone (see also Nature, Jan. 2, p. 26).

Geneva

Society of Physics and Natural History, November 5.

P. Rossier: (1) Observations of the comet 1936*a*. Photographs taken on July 23 and 29, 1936. The spectrum is of the normal cometary type, with carbon and cyanogen bands. (2) Relations between the colour index and effective wave-length of a star. Starting with an approximate expression for the index, the author shows that the colour index is a linear function of the effective wave-length, the coefficients of which bear a simple relation to the sensibility constants of the receivers considered.

Don Zimmet and Dubois-Ferrière: Vitamin C in human saliva, and paradentoses.

November 19.

P. Rossier: (1) Determination of the sensibility constants of receivers of radiant energy by means of scales of colour indices and of effective wave-lengths. The application of the theory of first approximation of the author to a particular case gives constants of the same order of magnitude as those determined by other methods. (2) Apparent character of a variation of a photographic extinction with atmospheric humidity. The variation of the sensibility of photographic plates with the humidity explains an extinction which the author had thought could be attributed to atmospheric absorption. (3) The star *BD* 4114 = *HD* 193092. Photographic observations of this star now suspected to be variable.

L. Meyer: Visual observations of Nova Lacertæ 1936.

Washington, D.C.

National Academy of Sciences (*Proc.*, 22, 621–672, November 15).

Edwin Hubble: Effects of red shifts on the distribution of nebulæ. A discussion of five surveys providing homogeneous counts of nebulæ leads to two opposed views. Assuming the displacements towards the red in the spectra of nebulæ are velocity shifts, the universe is closed, very small, packed with matter to the threshold of perception, and the rate of expansion has been slowing down. If the displacements are not velocity shifts, then the universe approximates to a homogeneous expanding model in which spatial curvature and rate of expansion are inappreciable. Presumably the 200-in. reflector will provide definitive tests between these models.

Felix G. Gustafson: Inducement of fruit development by growth-promoting chemicals. Such substances as indole-propionic, -acetic, and -butyric acids and phenylacetic acid, when applied in lanoline to the cut style of an ovary, cause growth resembling that resulting from fertilization, but no seeds were ever found. Mature fruits without seeds were produced in tomato, petunia, *Salpiglossus* and pepper.

William J. Robbins, Virginia B. White, J. E. McClary and Mary Bartly: Importance of ash elements in the cultivation of excised root tips. The addition to a nutrient solution of agar or filter paper, or water-extracts or the ash of either, even for a limited period (24–48 hours) increases the average growth of root tips 5–6 times. It is suggested that, since root tips have little store of ash elements, they should be useful for the study of mineral elements essential for growth in higher plants.

C. B. Davenport and William Drager: Growth curve of infants. It resembles that of a monomolecular autocatalytic reaction, but is modified by a period of accelerated growth at 6–8 months, and a period of retarded growth at 16–18 months. The growth curve is not controlled, even early in life, by any single reaction.

Donald F. Jones: Mutation rate in somatic cells of maize. While such mutations are an important factor in aberrant development, they are much less frequent than changes produced by somatic segregation.

Curt Stern and Dorothy Doan: A cytogenetic demonstration of crossing-over between *X*- and *Y*-chromosomes in the male of *Drosophila melanogaster*.

G. A. Miller: Number of the Abelian groups of a given order.

Chester Stock: Titanotheres from the Titus Canyon formation, California. This formation is of Oligocene age and occurs in the Death Valley region. Two specimens, one forming a new genus and species, are described and illustrated.

E. Wigner: Saturation of exchange forces.

A. van Harreveld and C. A. G. Wiersma: The triple innervation of the crayfish muscle. Two of the fibres identified appear to give contraction and the third inhibits it.

S. S. Stevens and E. B. Newman: The nature of aural harmonics. The aural harmonics were observed directly by analysing the electrical potential generated in the cochleas of animals by means of an oscillograph and a wave-analyser.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Saturday, January 30

British Mycological Society, at 11.—(at University College, Gower Street, London, W.C.1).—Symposium on "Antagonism of Micro-organisms" to be opened by Prof. W. Brown, discussion to be opened by G. Samuel.

Monday, February 1

Society of Engineers (at Geological Society), at 6.—A. S. E. Ackermann: "Scientific Paradoxes and Problems".

Armstrong College, Newcastle-upon-Tyne, at 6.30.—Prof. M. Polanyi: "The Transition State in Chemical Reactions" (Thirty-sixth Bedson Lecture).

Wednesday, February 3

Institution of Mining Engineers, at 11.15.—Annual General Meeting to be held in the rooms of the Geological Society, Burlington House, Piccadilly, London, W.1.

Queen Mary College, at 4.—Prof. F. E. Fritsch, F.R.S.: "Special Aspects of Algal Ecology" (succeeding lectures on February 10, 17, 24 and March 3).*

Thursday, February 4

Chemical Society, at 5.—Discussion on "The Transition State in Reaction Kinetics" to be opened by Prof. M. Polanyi.

Friday, February 5

Society of Chemical Industry (Glasgow Section).—Dr. J. T. Dunn: "The Service of Science to Industry" (Jubilee Memorial Lecture).

Royal Institution, at 9.—Dr. Stanley Kemp, F.R.S.: "Animal Life in the Antarctic".

Saturday, February 6

School Nature Study Union, at 3.—Thirty-third Annual Conference to be held at University College, Gower Street, London, W.C.1.

Prof. Walter Garstang: "The Songs of Birds".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Head of the Merton Central Evening Institute, Merton Park, S.W.19—The Registrar (January 30).

Assistant Tobacco Officer in the Department of Agriculture and Lands, Southern Rhodesia—The Official Secretary, High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, W.C.2 (January 30).

Forestry Assistant (Grade III) in the Forest Products Research Laboratory, Princes Risborough—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (February 3).

Assistant Lecturer in Science and Mathematics in the Liverpool City Technical College—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool, 1 (February 5).

University Lecturer in Anatomy in the University of Cambridge—Dr. F. J. W. Roughton, Department of Physiology (February 6).

Lecturer in Industrial Chemistry in the Cardiff Technical College—The Director of Education, City Hall, Cardiff (February 6).

Instructor Lieutenants (honours degree in mathematics, physics, chemistry or engineering) in the Royal Navy—Director, Education Department, Admiralty, 5 Millbank, London, S.W.1 (February 8).

Mechanical and Electrical Engineers (temporary) in the Directorate of Works and Buildings, Air Ministry—Secretary (W.B.9), Air Ministry, Adastral House, Kingsway, W.C.2, by postcard (February 8).

Senior Mechanical Assistants and Senior Electrical Assistants (temporary) in the Air Ministry—Secretary (W.B 9), Air Ministry, Adastral House, Kingsway, W.C 2, by postcard (February 8).

A Physicist in the Aeronautical Inspection Directorate, Test House, Kidbrooke, London, S.E.3 (non-metallic materials section)—Secretary, Air Ministry (S.2.D), Adastral House, Kingsway, W.C.2 (February 8).

Assistant Executive Engineer in the Public Works Department of the Federated Shan States, Burma—High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, by postcard (February 11).

Assistants (Grade II and III) at the Royal Aircraft Establishment, South Farnborough, Hants; *Ref.* 336*A*, for the writing of technical and descriptive matter; *Ref.* 327*A*, to assist in bench and flight testing, *Ref.* 314*A*, for structural strength and aerodynamic calculations—Chief Superintendent, Royal Aircraft Establishment, South Farnborough, stating appropriate reference number (February 12).

Director of the Fitzwilliam Museum in the University of Cambridge—The Vice-Chancellor (February 23).

Lecturer in Physics and Mathematics at the Croydon Polytechnic—Education Officer, Education Office, Katharine Street, Croydon (February 27).

Director of the Laboratory of the Freshwater Biological Association of the British Empire—Prof. P. A. Buxton, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1 (February 28).

Stevenson Lecturer in Citizenship in the University of Glasgow—Secretary (February 28).

Senior Lecturer in Social Anthropology in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (March 31).

Teacher of Mathematics and Science in the Junior Technical School of the Northampton Polytechnic, St. John Street, London, E C.1—The Secretary.

University Lecturer in Anatomy in the University of Cambridge—The Professor of Anatomy.

Assistant Civil Engineers in the Civil Engineer-in-Chief's Department, Admiralty—Civil Engineer-in-Chief, Admiralty, S.W.1 (mark envelopes "A C.E Decr.").

Civil Engineering Assistants in the Drawing Office, Admiralty, Civil Engineer-in-Chief's Department—Civil Engineer-in-Chief, Admiralty, S.W.1, marked D O.X.

Location of Industries

THE attention which, in the recent reports of the Commissioners for the Special Areas, has been directed to the attraction to, and the stimulation of, industry within those areas is only a particular example of the increasing interest which is being taken in the location of industry in Great Britain. The importance of rehabilitating the depressed areas of the country, whether those specially scheduled in the Special Areas Act or those other 'black spots' of the country such as the weaving and coal-mining areas of Lancashire, where unemployment is at least as great as in some of the Special Areas, and the signs of revival even less, is only one of many considerations bringing this matter to the front.

In his third report, the Commissioner of the Special Areas in England and Wales, while repudiating the idea of direct State control of the location of industry, advocated some measure of indirect control in the proscription of the location of industry in the London area, except for very definite and special reasons. Although this suggestion was intended to benefit the Special Areas, the argument rested at least as much on the relative vulnerability of London and the home counties, and the latter factor is obviously one of which increasing account must be taken unless we succeed in evolving a much more promising international order.

At the same time, the location of industry, like the planning of cities and towns, assumes greater importance from the increasing danger of destroying by indiscriminate building the amenities and beauty of our countryside. Ribbon-building has already done irreparable damage on both highways and coast, and unless effective control is exercised in these matters, as in questions of atmospheric or riparian pollution, little may be left to us of the rich heritage of rural England which was ours at the commencement of this century. Finally, transport considerations themselves are enforcing the consideration of the location of industry, so as to avoid the economic and social wastefulness and strain upon health involved in carrying immense numbers of tired people long distances to and from their work in overcrowded vehicles occupied only for a small fraction of the day.

Town planning, the location of industry, national health and defence, and the preservation of rural England, are in fact essentially different facets of one problem calling for long-range statesmanship and resolute scientific investigation. The strong criticism which the Government proposal to build an aircraft factory at White Waltham, near Maidenhead, received in the House of Commons, and the indignation which it aroused elsewhere, was due as much to the Government's countenancing Departmental violation of this principle as to the threat to the amenities of the Thames valley and the disregard of the claims of the Special Areas and the Commissioner's recommendations. Happily, the volume of protest, from all parties, was such that on January 26 Mr. Baldwin announced that the scheme had been abandoned, and that a new site will be sought in Lancashire.

It is not the least of the services performed by Mr. Malcolm Stewart, until recently Commissioner for the Special Areas, that he has so repeatedly emphasized the necessity for considering these areas as a problem of economic and social redevelopment on a very wide basis, calling for a definite national policy. The point is further stressed in an admirable broadsheet entitled "The

Location of Industry" which has just been issued by Political and Economic Planning (P E P) It is not merely that we are tending to consider the wider economic and social costs of different industrial policies and to realize the heavy offset to prosperity in the Midlands and South represented by wretched and paralysed groups of communities in Wales and the North. Increasingly we are coming to appreciate that there are definite opportunities of reconstruction and re-planning in the present situation, which, if wisely used, may involve almost as great benefit to the whole community as to any special section for whose benefit they are immediately initiated.

The Government itself has repeatedly emphasized the experimental character of the Special Areas Act. From the experience of the selected areas was to be crystallized all those methods which could be adopted in other areas suffering from heavy unemployment. The Special Areas were essentially a large-scale social experiment. On this point the valuable study "Re-adjustment in Lancashire"*, prepared by members of the Economics Research Section of the University of Manchester, bases one of its most powerful arguments for inclusion of the weaving districts of Lancashire within the Act. The present limits of the Act are arbitrary and convenient, rather than based rationally on economic or geographical facts, but can be justified for the purpose of an experiment so long as the experiment is representative. "Re-adjustment in Lancashire", however, seizes upon the point that the four areas so far selected are not representative of conditions in the weaving districts, because, unlike all the Special Areas, the rate of unemployment there is higher for women than for men.

The main importance of this most recent survey by the University of Manchester lies in the analysis and exposure of conditions in the weaving district. The case for including this area to obtain data for conditions not yet covered by districts already scheduled is presented with all the thoroughness, lucidity and impartiality which we have learnt to associate with the work of this Economics Research Section. There are, however, other matters bearing on the location of industry in Lancashire to which the investigation also directs attention. One of its principal suggestions is in regard to the establishment of a trading estate and the provision of capital at low rates to provide a favourable environment for local industrial enterprise, particularly with the view of attracting industries employing women. Special attention is directed to the possibility of the district becoming a large and growing centre for the clothing trades.

Former strictures upon blind-alley work, casual employment and the exploitation of young persons as well as of the unemployed in Lancashire generally are repeated, and the social evils which flow from an industry continually discarding its workers as they become older are still far from receiving the attention they demand. The possibilities and limitations of road construction in the area in regard to unemployment, of cleaning up the face of the country by demolishing derelict mills and similar measures are also considered, and the investigation makes it clear how little the re-armament programme can contribute to the solution of Lancashire's most intractable problems. This sober but impressive marshalling of the facts should at least assist to secure fair consideration for an area much greater in size than one or two of the Special Areas, and no less deserving.

If the investigation we have just discussed reveals the limitations of the present Special Areas Act, and the necessity for fresh schedules or for the rapid extension of the experience gained to other 'black spots' of unemployment, the need is emphasized for a national policy and above all for the consideration of the location of industry by creative minds free from prejudice and competent to take into account all the many aspects of national and social policy and well-being involved. The case for a national policy is the more imperative since its realization in practice depends upon the utilization of the opportunities of reconstruction and development afforded not merely in the Special Areas but also in special emergencies.

The most cursory glance at this problem should indicate how interlocked is this whole question of the location of industry and national reconstruction, and the importance of a central authority powerful and unbiased enough to secure action on behalf of the national and not sectional interests. The comparison cited in the P E P Broadsheet between the treatment of the Special Areas and the subsidizing of the sugar beet industry alone illustrates how disproportionate is our present policy, and the need for some wider co-ordination and vision. The wisdom of subsidizing the sugar beet industry has been attacked on scientific grounds, but however great the intrinsic merits of the sugar beet subsidy, it is difficult to defend the subsidizing in this way of a population of about half a million, in comparison with the treatment of a population more than eight times as great in the Special Areas and in considerably more desperate straits. Drift from the depressed areas will only be checked as it is made worth while for a sufficient proportion of the natural leaders who are thrown up in each area to stay in it happily, doing constructive work instead of becoming narrowed and embittered, and quitting it in favour of somewhere more attractive.

---

* Re-adjustment in Lancashire. By Members of the Economics Research Section, University of Manchester. Pp vii+137. (Manchester: Manchester University Press, 1936.) 4s. 6d. net.

The Special Areas are merely a particularly acute and painful example of the growing disequilibrium and sapping of vitality created by the excessive expansion of the metropolis. Moreover, years of mismanagement and neglect rather than sudden and unforeseeable misfortune are responsible for tragedies such as those of the coal-mining, cotton, fishing and sections of the agricultural industries, together with the areas mainly dependent upon them. The conclusion is inescapable that in future all major adjustments of policy should be examined not only with reference to their effects on the industry or other activity concerned but also with reference to their effects on the balance of national development. A constructively-minded Government, ready at the first signs of trouble to invest money in development work such as trading estates and new or improved communications, to bring in fresh industries or marketing measures and research to stimulate backward industries, could probably have salvaged many million pounds of expenditure in the last dozen years which has led the industry or area concerned no nearer a permanent self-supporting basis. "Re-adjustment in Lancashire" and the P E P Broadsheet are yet further reminders of the part which scientific investigation must play in the development of economic, social and industrial policy, and of the dire peril which attends neglect or failure to secure a more balanced national development and reconstruction in which internal strains between different areas and industries are minimized and a reasonable measure of social justice maintained.

The Science of English History

Roman Britain and the English Settlements
By Prof. R. G. Collingwood and J. N. L. Myres. (The Oxford History of England.) Pp. xxvi+515. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) *12s. 6d.* net.

THIS volume on Roman Britain and the English settlements is the first (though not the first to be published) in a series of fourteen covering the history of England, edited by Prof. G. N. Clark. The full-dress treatment of the theme commences with Cæsar's invasion, but this is preceded by a thirty-page introduction in which the geographical background and the prehistory of Britain are sketched in. Prof. Collingwood's contribution carries us through the Roman period into the fifth century; there Mr. J. N. L. Myres picks up the story, discussing that same century from the Anglo-Saxon point of view, and then the general problems of the English Settlement.

In 1910 Sir Charles Oman produced his very successful "History of England before the Norman Conquest". Though the new History is on a slightly larger scale, the two works are closely comparable, and it is interesting to see how they differ. Confining ourselves for the moment to the Roman period, Oman's survey is mainly military and political, based on documentary evidence (including coins and inscriptions). Collingwood, on the other hand, devotes more than one third of his pages to economic history and cognate studies. It is archæology that has made this possible in a period in many ways so ill-documented. The remarkable progress made by the science of the spade in recent years, and especially since the Great War, is familiar to all; a single contrast will bring it home. Some seventeen years work at Silchester, completed in 1906, laid bare the plan of a Romano-British town, but nothing else; on the other hand, three years work at Verulamium in 1932–34 revealed the history of an experiment in urbanization extending over nearly half a millennium, its growth, changes, vicissitudes and decay. On the military side, again, the post-War labours of field archæologists on the Roman Wall, at Richborough, Caerleon, Segontium and many other sites have given a new vitality and precision to the history of the army. The vigour of the development of archæology is also shown by the extent to which the natural sciences are drawn into the orbit of its research, and by the success with which novel techniques such as air photography are being exploited. All such aspects of field work are reflected in this volume, and help to mould its character.

Prof. Collingwood for many years has been one of the leaders of Roman studies in Great Britain, and speaks in this book with authority; he writes with that feeling for style which fortunately has never deserted the English historian. Special attention is due to his study of the interplay of life in town, in villa and in hamlet, and his exposition of the two agricultural methods employed in Roman Britain. The shift of the economic centre of gravity from town to countryside in the third century A.D. is seen to be a fact of prime importance.

Mr. Myres reverts to J. R. Green's method of approach, laying emphasis on the topography of Britain in relation to the English settlement. Recent studies in place-names and the history of institutions, and the attention now being devoted to Anglo-Saxon antiquities in their stylistic and distributional aspects, provide him with a range of data far wider than Green controlled. But the unresolved differences of opinion among contemporary scholars on many important aspects of his theme, the publication of Mr. R. H. Hodgkin's "History of the Anglo-Saxons" while his own was in progress, and the insufficiency of the available evidence, direct or indirect, combine to render his contribution less assured than that of his colleague. Nevertheless, it is an independent and acute study, embodying original research into the problems of a peculiarly difficult period; the section on the "Character of the Conquest" may be selected for special commendation.

To treat archæological material in the traditional historical manner, that is, with maps but without illustrations, offers a difficulty not hitherto surmounted. It was attempted for the "Cambridge Ancient History", but failed; for supplementary volumes of plates were issued at a later date. In this History, Prof. Collingwood's challenging thesis on Celtic and Roman art loses much from the lack of pictures; Mr. Myres, despairing of indicating verbally the quality of Anglo-Saxon art, "reluctantly omits" a review of the subject.

We have mentioned maps as essential to a history; and it is regrettable that the chief map in this book—that of Roman Britain—should be inadequate. The methods of symbolism adopted fail to bring out clearly the limits of the highland and the lowland zones of Britain, the importance of which is emphasized throughout the book; while the areas of naturally open country in the former zone (which it must be presumed the white areas on the map are meant to indicate) can scarcely be accepted as probable by anyone familiar with the geology and topography of, for example, Wales and the south-western peninsula.

CYRIL FOX.

Reactions in Uganda

Africa Answers Back
By H.H. Prince Akiki K. Nyabongo. Pp. x+278. (London: George Routledge and Sons, Ltd., 1936.) 7*s*. 6*d*. net.

As the work of a prince of the blood-royal of Uganda, who has been educated at Yale and Oxford, "Africa Answers Back", although in form a fictional biography, is a work which deserves more than casual consideration. It is significant as the mental reaction of an educated African to his contacts with European civilization.

In outline, the story runs: A son is born to an important chief, who has three hundred and seventy-five wives. The boy is educated in a missionary, and later in a private venture, school. His father dies in an epidemic of smallpox, which is stamped out by wholesale vaccination performed by a German doctor from Kiziba, Tanganyika, and doctors summoned hurriedly by drum from Mombasa and Zanzibar. The son is elected chief and introduces reforms, but is compelled to revert in part to traditional ways.

This thread of the story will indicate its limitations. The point of view is aristocratic. No attention is given to the social and economic problems of the people, which indeed in some ways are less insistent in Uganda than elsewhere in African administration. However, as a picture of the functioning of a great polygamous household and of the duties and ceremonial of its individual members, the book is more illuminating, even if less comprehensive, than most formal treatises.

Three contrasted points of view are presented with no little skill. First there is that of tradition, represented by the old chief, who, though open-minded up to a point towards the innovations Christianity would wish to introduce, is baffled by its inconsistencies, and convinced by his own line of argument that customary ways such as, for example, polygamy and birth control, are best for his generation, whatever a later generation may decide to do. Secondly, there is the missionary point of view, presented in a form rather out of date now, and, of course, as seen through native eyes. Thirdly, there is the point of view of the educated native, seen as it develops from the tribal attitude of the immature boy into the sophisticated and superficially acute outlook of the young man, who accepts the science of Western civilization as in most, but not all, respects superior to his own system, but is incapable of taking up the attitude of faith of that civilization.

The closing note is pessimistic. The missionary retires defeated. The hero, as a reformer, is regarded askance by his people, and as a monogamist, his single wife proving a shrew, is forced at her insistence to marry three or four more wives for the sake of peace in which to work out his plans.

Music in Films

Film Music:
a Summary of the Characteristic Features of its History, Aesthetics, Technique; and possible Developments. By Kurt London. Translated by Eric S. Bensinger. Pp. 280 +28 plates. (London: Faber and Faber, Ltd., 1936.) 12*s.* 6*d.* net.

IT is characteristic of our times that, while the abstract and practical aspects of transient political trends are over-documented in book form, the corresponding aspects of such permanently revolutionary factors in everyday life as broadcasting and the sound film are, on the whole, treated only in an ephemeral literature of specialized circles.

The attempt to make a balanced estimate of the inseparable technical and æsthetic problems of the sound film has not yet been made with any considerable measure of success. In the volume under notice, Dr. Kurt London succeeds in making us realize the profundity of the problems, but does not attain balance. He is described as a thinker, a musician and a technician; but his thinking stops short of the need for compelling the technician to be the slave of the musician. His error of outlook is shared by many distinguished musicians; it is implicit in Mr. Constant Lambert's introduction to this book, in which he says—apparently with some surprise and disappointment—that "Wireless has not so far compensated the composer by providing him with a new art form".

The book is in six parts, dealing in turn with "Origins of Film Music", "Music with the Silent Film", "Mechanical Interlude", "The Sound Film", "Training the Rising Generation" ("On the Establishment of a Microphone Academy") and "The Future of the Sound Film". On the technical side, the good description of the musical instruments in the sound film orchestra, and the good account of the limitations in reproduction imposed by the microphone and the rest of the recording and reproducing equipment, are in strong contrast with the poor exposition of the physics of recording. The author's brief treatment of the comparatively new electro-musical instruments, the *Ondium Martenot*, the trautonium and the Neo-Bechstein piano, is also good.

Dr. London's æsthetic judgment is sound, within its limitations. But he accepts far too easily the shackles of the average acoustic plumbing of the moment, and he neglects some of the most significant technical work of the decade. His imagination is misapplied in trimming the musician's mind and methods to fit the defects of the commercially available technique. He forgets that when babies and cradles do not fit, it is better to operate on the cradle. From this point of view, his interesting account of "microphone instruments", that is, "those constructed with a view to the special requirements of the microphone", is deplorable, as putting over-emphasis on this submission to the treason of the plumbers.

There is no valid ground for the assertion that an extension beyond 15,000 cycles per second of the frequency range reproduced would be of revolutionary æsthetic importance; the attention devoted to the sham 'stereoscopic' tone treatment of the French school is the more disproportionate because the conclusive experiments of the Bell Laboratories on binaural listening are not mentioned at all. It is firmly established by these experiments that true 'stereoscopic' listening, even with a very limited frequency range, is more satisfying than single-channel listening with a virtually complete frequency range. This omission emphasizes, too, the singular absence from the book of any reference to Stokowski, who has collaborated so fruitfully with the Bell Laboratories, not only on binaural listening but also on the utilization of the new powers which electrical reproduction puts at the disposal of the musician, in part-compensation for the disservices which it does him in other respects. Of all these disservices the greatest, in everyday practice, is the simple amplitude distortion which is not inherent in present technique, which is not mentioned by Dr. London, but makes a visit to any single cinema theatre definitely painful to a musicianly or acoustico-physical ear.

The author and the translator are responsible for some offences to the King's and the physicist's English; he uses the words "resonance", "tone" and "dynamic" inaccurately, as many people will.

It is perhaps too late to hope that the "recordist" may join the mortician, but it is not too late to kill the adjective "microgenic". The translator comes near distortion, for the ordinary reader, when he renders "Plastik" as "plastic", and goes beyond it for the ordinary viewer when he talks of a film called "President Vanisher".

The author's philosophy of film æsthetic is somewhat superficial, a fair recognition of the validity of expressionism in the music being marred by over-insistence on representationalism in the picture. To talk of the hand-written sound-track, with its vast possibilities, at some length is wise and discriminating ; to talk of it as "quite unreal sound", "a magic realm created out of nothing" is nonsense. The Beethoven symphonies were "quite unreal sound", "a magic realm created out of nothing", in exactly the same sense ; the orthodox score, the photographed sound track, and the hand-written track are all of them arbitrary notations containing, for the initiated, the prescription for producing real sound out of unreal sound.

Dr. London's book is the more welcome in giving so much enjoyable ground for disagreement ; it is attractive, suggestive and educative. No one who recognizes the power of the sound film in modifying the taste of the citizens of to-day and to-morrow can afford to neglect it. Its attractions are enhanced by the many facsimile reproductions from film-music scores.

Science in Recent Years

The March of Science : a First Quinquennial Review, 1931–1935. By Various Authors. Issued under the authority of the Council of the British Association for the Advancement of Science. Pp. viii +215. (London : Sir Isaac Pitman and Sons, Ltd., 1937.) 3*s*. 6*d*. net.

THIS book is the first of a new series of volumes wherein, it is intended, the advances made in the chief branches of pure science over a period of five years will be described in plain language by experts. These books are intended both for ordinary readers of scientific tastes and for those workers in any one branch of science who would like to learn with a minimum of trouble what is new and important in other branches. The style and difficulty is, in consequence, somewhere between those of the illustrated popular expositions and the learned reports for the specialist in his own science. Editors and publishers have attempted this kind of books in the past, sometimes with success, but it is good news that the Council of the British Association with its wide knowledge of the right contributors has now begun this work. The chief difficulty of such enterprises is, of course, in getting the best men to take the peculiar trouble which semi-popular exposition demands.

The present volume deserves a warm welcome from readers. It is rare that a permanent work, so homely in appearance, has such distinguished contributors. There are no illustrations. The price is modest. There are sixteen chapters or sections (varying from 2,500 to 6,000 words in length) by different writers, each of whom is distinguished in his own subject. Nearly all of these have done the journeyman work of compiling and writing satisfactorily, and some have done it very well. On the whole, the more eminent authorities have done their tasks better than the less. The sections on cosmical physics (Sir James Jeans), economic science (Sir Josiah Stamp), biochemistry (Sir F. Gowland Hopkins), and science and industry (Sir Frank Smith) are models of the thing required—apposite, informed, fair, well-expressed, neither too technical nor too popular for the readers envisaged. The important discoveries or developments in these subjects in the past five years are singled out and well described. The reader who has, perhaps, heard vaguely of some of these in talk can now know where the main interests of a diversity of subjects lie, what has been proved, what is still speculation, whither progress is tending and how good are prospects. Good also, although less distinguished, are the sections on geology (P. G. H. Boswell), geography (G. R. Crone), educational science (A. Gray Jones), agricultural science (J. A. S. Watson) and physiology (L. E. Bayliss).

It is chiefly in the sections on physics and physical chemistry that a bareness of treatment is revealed. Chemistry has sections on 'physical' and 'organic'. The former, however, should more properly have been called 'general'. The section is good as that, but it contains little of the advances in subjects like gas reactions, photochemistry, solution, catalysis. The writer on physics had a peculiarly hard task within his limits of difficulty and space. (Two sections might well have been allotted to this large field.) Unfortunately, however, he opened with an account of nineteenth-century physics, excellent in itself but largely irrelevant there, and so left himself too little space for some of the important revelations of the past five years. Dr. de Beer, on the other hand, has perhaps erred by excess of zeal. Compared with the other sections, his on zoology is too full, too well documented. But it cannot be criticized on other grounds.

A. S. R.

Preparation of Scientific and Technical Papers

By Prof. Sam F. Trelease and Emma Sarepta Yule. Third edition. Pp. 125. (Baltimore, Md.: Williams and Wilkins Co; London: Baillière, Tindall and Cox, 1936.) 7*s*.

MANY useful hints on the composition of scientific papers, and methods of presenting observations and results logically and precisely, are given in this small volume. Much practice, combined with a sense of literary values, are required for the production of a scientific paper to satisfy all the canons of style which writers are expected to acknowledge. There are, however, many typographical and other conventions which every author should know; and it is particularly in guidance as to the use of these that this book will be helpful.

We note that in the list of abbreviations of common weights and measures, and elsewhere in the book, "cc" is given for cubic centimetre; but, as actually two words are abbreviated, "c.c." is the correct form. The classified titles of a number of scientific periodicals are given in another list, but we miss several British publications of greater importance than some others included. Under anthropology, *Africa* is included but not the *Journal of the Royal Anthropological Institute*; and among other omissions are: the *Quarterly Journal of Microscopical Science*, the *Journal of the Chemical Society*, and the *Philosophical Magazine*, while *Science Progress* is wrongly described as "Science Progress in the Twentieth Century". It is very difficult to make up a list of this kind, and impossible within the space of about nine pages to give more than a few representative titles of the many thousands of scientific periodicals now published. We suggest, however, that, before the next edition of the book is issued, the lists of journals grouped under headings relating to various branches of science should be submitted to competent authorities in each branch for revision.

The King's England:

a New Domesday Book of 10,000 Towns and Villages. (1) Enchanted Land: Half-a-Million Miles in the King's England. By Arthur Mee. Pp. xviii+291+65 plates. 7*s*. 6*d*. net. (2) Kent: the Gateway of England and its Great Possessions. By Arthur Mee. Pp. xii+506+65 plates. 10*s*. 6*d*. net. (3) Warwickshire: Shakespeare's Country. Edited by Arthur Mee. Pp. xi+308+49 plates. 7*s*. 6*d*. net. (4) Lancashire: Cradle of our Prosperity. Edited by Arthur Mee. Pp. viii+326+49 plates. 7*s*. 6*d*. net. (London: Hodder and Stoughton, Ltd., 1936.)

THESE four volumes are the first instalment of a survey of England by counties, which aims at describing in detail every town and every village in the country which is worthy of interest on account of its present economic or social importance, its past historical or personal associations, or its retention of features of artistic, antiquarian or cultural significance. The author has had the assistance of a body of expert helpers; and some six years have been spent in preparation. The time is not too long, as some ten thousand villages, it is said, have been visited. The collection of the photographs alone, if the illustration of the first four volumes is a fair sample, must have been a stupendous undertaking, especially as it is evident that on the whole a high standard has been attained.

Except in the first volume, which is a generalized epitome or survey of the topics with which the series deals as a whole, the arrangement of the material collected is that of the gazetteer. Each city, town or village visited appears in alphabetical order, the counties being characterized in a brief introduction, in which what is taken as the keynote is particularized, justified and expanded, though not at too great length. Kent, for example, is termed "the gateway of England", Warwickshire, "Shakespeare's country", and Lancashire, "the cradle of England's prosperity".

Yet in none of these volumes is this dominant note allowed to overshadow other interests. In Warwickshire, Birmingham and Coventry are not neglected, nor is Lancashire's industrialism allowed to obscure the relics of its ancient countryside or its interest for the student in Roman Ribchester and the wooden circle of Bleasdale. Mr. Mee is happiest, however, in rural Kent or Warwickshire, or in writing his general volume when he can roam about in the past among obscure villages with their ancient churches and family monuments, as well as their unexpected and their often surprising associations with some of the famous personages of history, social and literary no less than political.

Those of like tastes will roam with Mr. Mee with equal zest. It is a course of very mixed feeding, which will seem reprehensible to the formal historian and educationist. But it is very enjoyable.

School Certificate Chemistry

By A. Holderness and J. Lambert. Pp. x+414. (London: William Heinemann, Ltd., 1936.) 4*s*. 6*d*.

THIS is a pleasing book profusely illustrated by photographs and line drawings, the latter being unusually clear and instructive. The atomic and molecular theories are given careful attention and the authors have succeeded in making clear a section which most pupils often find rather difficult. The metals are treated in a somewhat original manner, the authors using a classification based on the electrochemical series instead of the usual periodic classification. The salts are grouped according to acid radicals instead of metals, the sulphates, for example, being described in the chapter on sulphuric acid.

Each chapter is provided with a set of questions, and there are general questions at the end of the book, preceding a list of atomic weights and a table of logarithms. A useful feature is the final chapter of twenty pages devoted to revision notes and definitions, which contains some good general advice to young pupils about to present themselves for examination. This is certainly a book which pupils and teachers alike will enjoy using. The consistent use of arrows instead of equals signs in equations will not commend itself to teachers, who find that this practice leads to carelessness in balancing equations.

Jan Swammerdam, 1637-80

By Prof. F. J. Cole, F.R.S.

JAN SWAMMERDAM was born at Amsterdam on February 12, 1637, and died there on February 17, 1680. He was the son of a prosperous apothecary, Johan Jacobsz Swammerdam, with whom he is frequently confused, and the grandson of J. Theodorus, who assumed the name of Swammerdam, and was born in the Dutch village of Swammerdam or Swadenburgerdam (now Zwammerdam) on the Old Rhine.

The pseudo-learned atmosphere of his father's private collection of rarities, which included minerals, fossils, plants, animals, manufactured and artistic curiosities and coins, the animal section forming about a sixth of the whole, could scarcely have been responsible for the rigorous scientific attitude towards natural knowledge which was characteristic of Swammerdam himself. His father intended him for the Church, but he embarked upon the study of medicine, only to be diverted from it by his passion for entomological research. Finally, however, he completed his medical course and graduated M.D. at Leyden in 1667. In the meantime, he had become friendly with his famous contemporaries Steno and de Graaf, but later his relations with de Graaf were embittered by a controversy on the structure of the genital organs. Also before graduation he had visited France, where he was befriended by Melchisedec Thévenot, and continued his entomological investigations. It was here that he publicly demonstrated the valves of the lymphatic vessels on June 19, 1664 (published 1667), but in this he was anticipated by another Hollander, Frederik Ruysch, who issued a detailed description of the valves in 1665.

On returning home, Swammerdam participated in the foundation of the private Amsterdam "College" of Medicine. This company of enthusiasts printed small volumes of transactions in 1667 and 1673, which are now exceedingly rare, and to which Swammerdam himself contributed. He was thus for the time committed to human anatomy, and experimented with methods of injection, inflation and preservation. He did not, however, invent *solidifying* coloured injection masses, as is generally stated, but he was responsible for the general adoption of the method by anatomists after his time. His first wax injection was carried out in van Horne's house in Leyden in 1666. It was probably in 1671 that he sent to the Royal Society, accompanied by descriptions and figures (published in 1672), his famous preparation of the human female genitalia. Arteries and veins had been injected with yellow and red wax, which acted as a preservative, and the whole was then dried. The Royal Society's collection was handed over to the British Museum in 1781, and this historic specimen was never again seen. Later, Swammerdam applied the injection method to the smaller invertebrates, and he succeeded in filling the blood vessels of a Lepidopterous larva from the heart by means of a capillary glass tube.

After an illness, Swammerdam abandoned human anatomy, and thenceforward devoted himself entirely to comparative anatomy, chiefly of insects. Such a devotion to science absorbed not only all his time and attention, but also was expensive, and his father penalized the neglect of a profitable profession by cutting off supplies. To mollify his angry parent, Swammerdam wasted much valuable time in cataloguing the family museum, and this catalogue, which was published in 1679, shows that the collection was not comparable with many others which existed in Holland at the time.

In 1673 Swammerdam came under the disturbing influence of Anthoinette Bourignon, and henceforward his interest in science began to decline. It flared up from time to time, but the process of extinction had set in. Finally, he convinced himself that the pursuit of learning was vain and even impious, and he died in an atmosphere darkened by the turmoils of an unbalanced mind. Nevertheless, it was during this period of strife that he completed his classic treatises on the honey-bee and the mayfly, working, as the rhetorical Boerhaave tells us, exposed bareheaded to the scorching heat of the sun and "dissolving into sweat under the irresistible ardours of that powerful luminary".

The early death of Swammerdam was not entirely responsible for the fact that the bulk of his work remained unpublished, for to his own indifference were added the apathy and neglect of his successors. The manuscripts passed first into the hands of Thévenot, who designed to publish them, but he died without discharging this important trust. After some vicissitudes, the papers were acquired by G. Duverney, the celebrated Parisian anatomist, who had already undertaken other charges of a similar nature, but lacked the desire to liquidate any of them. Finally, Boerhaave was moved to intervene, and in the subsequent proceedings he played an important and honourable part. He purchased the documents from Duverney, and published them under his own guarantee as two imposing folio volumes in Dutch and Latin in 1737–38, exactly a century after the birth of their author, but nevertheless not yet out of date ! It is painful to reflect that Swammerdam's own collection of preparations shared the common fate of the museums of his period, and, having failed to attract a purchaser, was dispersed. Unlike his great contemporaries, Malpighi and Leeuwenhoek, Swammerdam was not a fellow of the Royal Society ; but he corresponded with the Society, the archives of which include some material in his autograph. One genus (1826) and some ten species of insects have been named after him.

The picture which the evidence justifies us in forming of the personality of Swammerdam, is that of a man with an introspective and self-torturing mind which found expression sometimes in pompous and scornful criticism of others, but more often in the superfluous distractions of mysticism and spiritual exaltation. Add to this a consuming energy which produced, in some ten years before the age of forty, one of the most remarkable works in natural history which has ever been written, and also an indifferent physique wasted from time to time by fevers, and the result could only be a life which rapidly burnt itself out. His strength in research lay in observation and experiment. In reflection he was dangerous, and apart from the fact that he was a convinced and uncompromising opponent of spontaneous generation, which was incompatible with his belief in preformation, no important generalization can be associated with his name. No portrait of him is known to exist. That reproduced by Michelet and others is a forgery based on one of the lay figures in Rembrandt's "Anatomy Lesson" of 1632, the model of which could not have been Swammerdam.

The methods employed by Swammerdam in his finer work have been partly disclosed by Boerhaave. He used a simple dissecting microscope of his own design, made by Samuel J. van Musschenbroek, and very delicate dissecting instruments sharpened under the microscope. He was one of the first naturalists after Boyle to appreciate the importance of alcohol as a preservative, and was probably the first to make dissections under water, and to clear up an entomological preparation by dissolving out the fatty substances. The modern practice of preparing Lepidopterous larvæ for exhibition by pressing out the viscera and inflating and drying the skin was invented by Swammerdam.

In addition to various Parerga to be found in the works of T. Bartholini, sen., Thévenot, van Horne, Blasius, Boccone, Steno, the *Philosophical Transactions* and the works of the Amsterdam "College", Swammerdam published four major works during his lifetime. The first of these, an inaugural dissertation on respiration, was published in 1667 in Latin, and five other Latin editions appeared later. In 1927 the first edition was re-issued in Holland with a Dutch translation. This little treatise has considerable physiological importance. The discovery of the part played by air in respiration may here be recognized in one of its earliest phases, and the mechanism of mammalian respiration is ingeniously demonstrated by means of a pair of bellows containing the wind-pipe and lungs, in which the action of the bellows on the lungs can be observed through a glass window cut in the side. As pointed out by Patterson, this idea was adopted without acknowledgement by Mayow in 1674. In the interests of priority, it should also be recorded that Swammerdam's experiment had been published for thirteen years before Borelli issued the first volume of his "De Motu Animalium".

Swammerdam was among the earliest to test the effects of injecting the vessels of *living* animals, and his discovery that the mammalian lung sinks in water before it has functioned, but floats afterwards, has important medico-legal bearings in cases of suspected infanticide. Significant observations on clinical and chemical thermometers are also to be found in this remarkable thesis, and even topics foreign to its express purpose, such as the hermaphroditism and reciprocal union and fertilization of snails, are not excluded.

Swammerdam's first entomological publication, which later formed a part of the "Biblia Naturæ", was his "General History of Insects". It appeared in 1669 in the Dutch language, and was followed by five other French and Latin editions. A few years later, in 1672, the work on the uterus was issued, and went through eight editions, all of them in Latin. It includes the polemic against de Graaf, but is important from the point of view of anatomical injections and the preformation doctrine.

The treatise on the mayfly was first published in 1675 in Dutch—six years after Malpighi's treatise on *Bombyx*—but only two other editions, in English and French respectively, appear to have been printed. To Anthoinette Bourignon the mayfly was a "little beast which lives for only a single day, and throughout that time endures many miseries". She gave, however, a grudging consent to the printing of the book, but implored Swammerdam to devote himself in the future to the more serious things of eternity. In this expansive and verbose work Swammerdam followed the lead of Servetus, and undertook the dubious task of establishing an ethical system which united the diverse interests of biology and divinity. In spite of the fact that it had a numerous following, amongst whom may be mentioned Lesser in Germany and Kirby and Spence in England, insecto-theology, as it was called, fell an inevitable victim to its own disruptive elements The biology of the work, however, greatly diluted as it is, shows us Swammerdam at his best. He appears to have started work on the mayfly as early as 1667. The anatomy of the small nymph is beautifully worked out, and in this respect Swammerdam is clearly superior to Malpighi. In addition, the curious life-history, in which the brevity of the adult stage is contrasted with the exceptionally long larval period, is laid bare for the first time. This work is also included in the "Biblia Naturæ".

The posthumous "Bible [not Book] of Nature" owes its name probably to its sponsor Boerhaave, and the detailed and accurate plates are the work of an artist employed by the author. One of the Ephemera plates, however, is signed "Auctor del". In all, eight editions were published, including German, French and English translations. It is impossible in this brief notice to refer to more than a few of the topics which are investigated in this stupendous work. Its plan, based on selected types, is monographic, comparative and experimental, and it is undoubtedly the foundation of our modern knowledge of the structure, metamorphosis and classification of insects. In addition, there are valuable observations on Crustacea, Mollusca and the life-history and anatomy of the frog in both larval and adult stages. Swammerdam spent some five years on the hive-bee, dealing with the anatomy, life-history and general economy of that much investigated animal, and his account of it is the most trustworthy and comprehensive we have had from any one man. It would, in fact, rank high even if judged by modern standards. In 1668 Swammerdam had already discovered by skilful dissection that an insect larva, pupa and imago may *at one stage* of the life-cycle exist simultaneously one within the other like a nest of boxes, and he had also studied experimentally the conditions which induce and regulate moulting and metamorphosis. His consequent assumption that no new parts are formed, and that the perfect insect is there *all the time*, led him to adopt the Preformation doctrine, the long and evil reign of which lies so heavily on his reputation. Swammerdam severely criticizes Harvey's views on metamorphosis, esteeming him at "little less than nothing", and stating that his work on generation contains almost as many errors as words. Harvey's philosophy of generation may have been, as Vallisneri says, "encrusted with Aristotelian pitch and heavy with rust", but it was the deadly blight of Preformation that stopped the clock.

Swammerdam accidentally stumbled upon the mimetic resemblance of certain Diptera to bees, and he found that some Lepidopterous egg masses might give rise to flies instead of caterpillars, which is the earliest record of egg parasites. He observed also in the case of the frog the first cleavage of the ovum, and noted the cellular structure of later stages. He admits, however, that blood corpuscles had been known for "some years" before he saw them, but does not give the source of his information, which could scarcely have been Leeuwenhoek. He certainly found the oval blood corpuscles of the frog before Leeuwenhoek. His ingenious neuro-muscular preparation (1668) by which he studied the relation of muscle and nerve, and the nature of muscle contraction and the nerve impulse, enabled him to refute the current belief that muscular action was due to a material substance reaching the muscle via the nerves, and in his experiments on the contraction of the heart and muscle he invented a form of plethysmograph. These results alone would entitle him to be regarded as one of the founders of experimental biology. But to the discoveries which are to be found in the "Biblia Naturæ" there is almost no end.

Chemical Exploration of the Stratosphere*

By Prof. F. A. Paneth

OUR prospect of finding differences in the chemical composition of the air is, of course, better the higher the sample is obtained in the stratosphere. An important part of the whole research is therefore the collection of air samples from great altitudes. For this purpose, sending up automatic devices in unmanned balloons is the most efficient method. Aeroplanes cannot attain sufficiently high altitudes; even Squadron Leader F. R. D. Swain in his record flight last September reached only 15 km., and the inconveniences of an airtight suit preclude complicated scientific operations. Balloon ascents in closed gondolas, as introduced by A. Piccard in 1931, give more freedom for observations, and can attain greater heights. A year ago, Capt. Stevens and Capt Anderson in a stratosphere flight arranged by the National Geographic Society and the U.S. Army Air Corps reached 22 km.; but it cannot be said that the scientific results of the expedition justified the immense costs. The varying conditions of the atmosphere make numerous observations necessary, and only the cheap flights of sounding

* Continued from p. 182

balloons can be repeated frequently enough; moreover, they can ascend far higher than manned balloons. (Heights of more than 30 km. have been recorded.) Fig. 2 shows the altitudes so far reached by the most successful flights of aeroplanes, manned and unmanned balloons. The flights from which air samples have been brought back are underlined. A number of other air samples collected by sounding balloons are not recorded in the figure; the heights attained can be seen in Table 3.

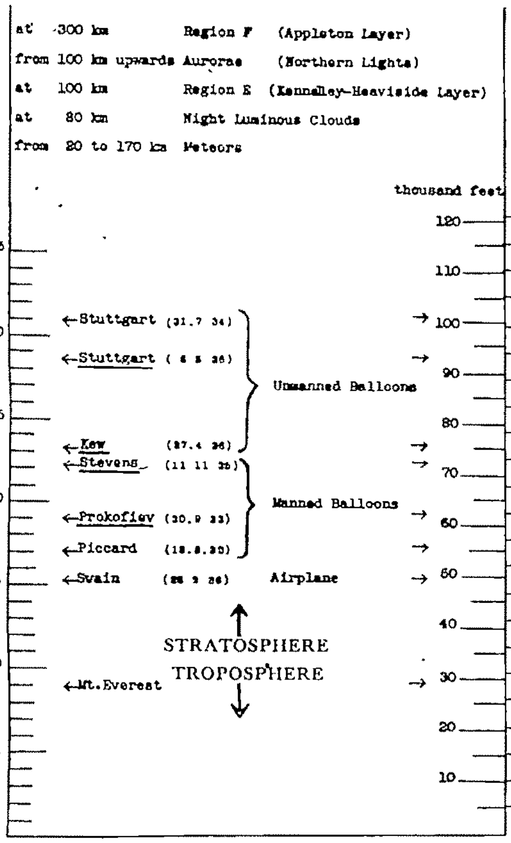

Fig. 2.

Chart of stratosphere flights. Air samples were obtained on those which are underlined.

For the automatic sampling quite a simple device is sufficient. The one used in the joint work of the Meteorological Office of the Air Ministry, and Dr. Glückauf and I working at the Imperial College of Science and Technology, is represented in Fig. 3. A detailed description has been given by Mr. L. H. G. Dines of the Upper Air Section of the Meteorological Office, who launched the balloons from Kew Observatory[1]. The device comes into operation after the sounding balloon has burst at the top of its flight; an extension of an evacuated glass bulb is then broken, and air is sucked in while the vessel, attached to a parachute, begins to fall; after an interval of 10–15 sec. the extension is sealed again. In Fig. 3 on the right-hand side are to be seen the parachute, the bamboo cage and the aluminium cylinders which contain the glass vessel and a Dines barothermograph; on the left side are the glass vessel (volume about 500 c.c.), and the electrical arrangement for breaking the extension and for sealing the bulb again; this latter is effected by means of a heating coil which surrounds the lower part of the glass stem and fuses a particular kind of sealing wax contained inside. If the mechanism functions satisfactorily, the pressure of the air inside the vessel should correspond within certain limits to the highest value of the barographic record.

These flights have been in progress since 1935. From the first results, published a year ago[2], it was concluded that up to 18 km. no definite change in the chemical composition of the stratosphere occurred, but that at a height of 21 km. the relative amount of the light gas helium is already distinctly increased. During the past year, this has been confirmed by further successful flights reaching more than 23 km.[3] Similar investigations have lately been carried out by Prof. E. Regener in Stuttgart[4], using larger balloons; in his samples, one from a height of more than 28 km, he determined the oxygen content and found deficits, in

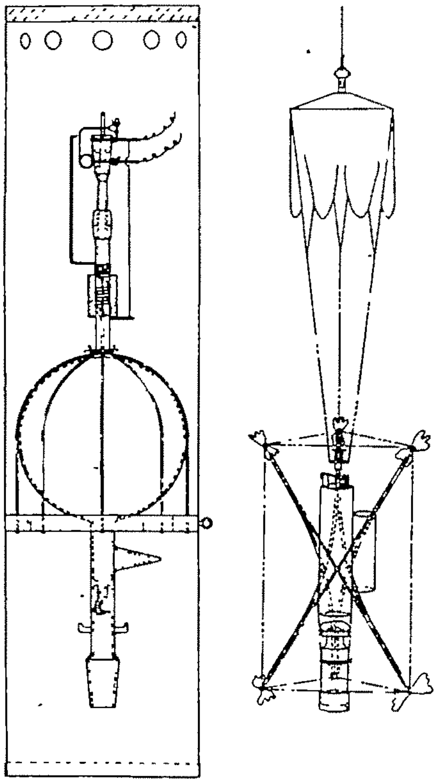

Fig. 3.

Apparatus for sampling stratosphere air.

good agreement with the helium surpluses detected in the London flights. The only two air samples obtained by manned stratosphere balloons also confirm our finding: a sample collected over Russia by Prokofiev in 1933 at a height of 18·5 km., and analysed by A. A. Čerepennikov and by A. B. Moskvin, showed no variation in its composition[5]; but the air brought back by Capt. Stevens from 21·5 km., and analysed with great accuracy by M. Shepherd[6] of the National Bureau of Standards in Washington, revealed a slight oxygen deficit

TABLE 3.

HELIUM AND OXYGEN CONTENT OF THE ATMOSPHERE AT VARIOUS ALTITUDES.

Height in km.	Helium[2,3]		Oxygen	
	Per cent by vol	Variation (per cent He)	Per cent by vol	Variation (per cent O_2)
0	$5·27 \times 10^{-4}$	0	20·945[8]	0
			20·92[4]	0
9–16·8			20·92[7]	0
14·5			20·89[4]	−0·14
16·7	5·30	+0·5		
18·5	5·31	+0·7	20·95[5]	0
			20·84[4]	−0·38
19			20·87[4]	−0·24
21	5·64	+7·0		
21·5			20·895[6]	−0·24
22	5·49	+4·1	20·57[4]	−1·7
	5·53	+5·1		
23·4	5·49	+4·2		
24			20·74[4]	−0·86
28–29			20·39[4]	−2·5

In Table 3 all reliable data about the helium and oxygen content of stratosphere air are brought together. In addition to the results already mentioned, the figure found by Lepape and Colange[7] for the average oxygen content of samples collected between 9 km. and 16·8 km. is also included; they observed no deviation. According to the same authors the helium plus neon content at this height varies considerably (as much as 57 per cent), and on the average is increased by 27 per cent; the method applied was, however, not reliable. Our results show the constancy of the helium, and therefore *a fortiori* the neon, content at these heights within one per cent.

The deviations in the helium and oxygen content of the higher layers of the stratosphere, revealed by the figures in Table 3, from those in the troposphere, are in the direction to be expected if at a height of about 20 km. winds are no longer efficient enough to ensure a complete mixing of the atmospheric gases. The 'light' gas helium is present in a higher, the 'heavy' gas oxygen in a lower, percentage. The difference is more marked in the case of helium; this is in good accord with the greater density difference between helium and the main atmospheric gas, nitrogen (see Table 2).

Here, however, the possibility of generalizations ends. Calculation shows that a height of 1 km. in an undisturbed atmosphere should lead to an increase of the helium value of more than 13 per cent, and to an oxygen deficit of about 1·6 per cent. Now neither the London nor the Stuttgart samples show a gradual change in the composition of the air in proportion to altitude; and the changes found are much smaller than would be expected if from 20 km onwards there were perfect quietude This leads to the conclusion that there is by no means a sudden change in the conditions of the stratosphere at this height, but that the influence of air currents becomes only gradually less, and is dependent on weather conditions. We cannot therefore expect exact correspondence between the helium and oxygen values of air samples, collected on different dates and from different geographical areas; we intend to determine both values for one and the same air sample in order to test whether the changes found are actually due to gravitational separation.

It may be mentioned that air samples from heights of 18·5 km. and from 21·5 km. have been analysed for hydrogen by Čerepennikov, Moskvin and Shepherd Even at these heights none was found. Previously meteorologists, misled by unreliable chemical analyses, took for granted the presence in the troposphere of measurable quantities of hydrogen, and demonstrated by calculations that the upper part of our atmosphere should therefore consist almost entirely of hydrogen. Some even went so far in hypothetical speculations as to postulate the presence there of a still lighter element, christened 'geocoronium' or 'zodiakon'. This, and particularly the 'hydrogen sphere', is still mentioned in many text-books. G. Ch. Lichtenberg, professor of physics in Göttingen a century and a half ago, must have had similar cases in mind when he wrote: "Perhaps Hamlet is right that there are more things in heaven and earth than are dreamt of in our philosophy; but on the other hand it may be said that there are a good many things in our natural philosophy books of which neither in heaven nor on earth any trace can be found."

When we started work two years ago on the helium content of stratosphere air, it was quite unknown whether it would be possible to reach a layer where any variations from the composition of ordinary air occur. The only accurate figure about stratosphere air then available, the oxygen analysis of air from 18·5 km. height, collected and analysed by the Russian investigators, showed not yet the slightest difference from ordinary air. Since last summer, we have been certain that from about 20 km. upwards the composition of air changes to a measurable extent. Much further work will be necessary before we are able to formulate the rules governing these changes. But as the question of stratospheric air movements may be also of some practical importance for weather forecasting and for aeronautics, we hope to continue, and to extend, our researches.

Obituary Notices

Sir John Bland-Sutton, Bt.

SIR JOHN BLAND-SUTTON, BT., president in 1923–25 of the Royal College of Surgeons of England, and consulting surgeon to the Middlesex Hospital, who died on December 20 last, was born in 1855. Since John Hunter, no pathologist-surgeon of equal eminence has arisen in Great Britain, and like his prototype he approached surgery through the study of anatomy and comparative anatomy. Like Hunter, too, he was brought up in the country, and school played a less prominent part in his education than his own sharp eyes and sceptical curiosity. Unlike Hunter, he was not an experimentalist. He was more preoccupied with naked-eye form than with histology or physiology, though he always studied morphology in relation to function and to the evolutionary process.

It was not until he was twenty-three years of age that Bland-Sutton, already a skilled naturalist, first determined to be a surgeon. Poverty in youth teaches a man that independence, the power to help others, free choice, and the avoidance of jarring contacts are unattainable unless one does something that the world needs and is willing to pay for. In surgery Bland-Sutton found a field for his talents and for applying his mastery of anatomy and pathology. He entered as a student of the Middlesex Hospital in 1878, and in the following year was appointed demonstrator of anatomy. As an anatomical teacher he achieved great popularity, and in 1886 he was appointed assistant surgeon, becoming surgeon in 1905 and consulting surgeon in 1920. Throughout life, he remained devoted to the Middlesex Hospital, to which in 1914 he presented the complete pathological institute which bears his name. It was significant of his forward outlook that the space allotted to the museum in the new building was reduced so that more scope could be given to the experimental and histological laboratories.

In 1896, Bland-Sutton was appointed surgeon to the Chelsea Hospital for Women, and it was in gynæcological surgery that he made his name. For years this branch of surgery was practised by physicians—a curious anomaly having its roots far back in history. Spencer Wells and his successors at the Samaritan Hospital had broken through the tradition, and some obstetric physicians were good surgeons, *vixerunt fortes ante Agamemnon*, but the main credit for bringing pelvic surgery up to the level of general surgery unquestionably belongs to Bland-Sutton. He more than any man disestablished the 'couch-invalid' formerly seen in so many families—generally a woman with fibroids, an ovarian tumour, or the sequelæ of pelvic inflammation. Striding into this field where the crop had been ripening through many tedious years of invalidism and inaction, he rapidly acquired a very large and beneficent practice. His operating afternoons at the Chelsea Hospital for Women attracted surgeons from all over the world. At the same time, in his capacity of surgeon to the Middlesex Hospital, the hospital in which he was nurtured and which he always loved, he continued the practice of general surgery.

As an operator, Bland-Sutton was rapid and safe, though some critics considered him lacking in the refinements of technique. His results were excellent. Surgeons, like the clergy, may perhaps be divided into two classes, ritualists and evangelicals. Some love complicated instruments and elaborate technique; Bland-Sutton liked to reduce his instrumental and aseptic outfit to the minimum essential for the job in hand. Moreover, as a pathologist he realized that Nature is the real surgeon, while the surgeon is a kind of 'plumber's mate' to Nature. He never wasted time in doing things that Nature would do better herself. Perhaps in sewing up the abdominal wall with a single layer of sutures he sometimes trusted her too much.

Bland-Sutton had a vigorous common-sense mind which always led him to seize on the essentials of a subject and to press direct to a conclusion which was generally the right one. His mental vigour always seemed to maintain a constant level, so that in the spare quarters of an hour which most men waste, he could add a few lines to any paper he was writing. *Nulla dies sine linea* was a favourite quotation. His mental energy demanded satisfaction in constant work, and needed no whipping up to the task. Few men have done more work in a lifetime, and few have done it better. He said he could only learn by the eye, and noted in himself an entire absence of the mathematical faculty, nor I think did music appeal to him. His letters, always brief and pointed, were written in a clear and unhurried hand, and so far as I know he never employed a secretary, a typewriter or a dictaphone. From his boyhood's intensive Bible lessons, for his aunt intended him for the Church, and from the study of Shakespeare, he derived a distinctive literary style, concise, arresting, and seasoned with an occasional archaism or blunt Anglo-Saxon word. It may have been the foundation of his friendship with Kipling that both men were students of the art of expression.

Bland-Sutton once said to me in reference to a very large text-book : "It is very easy to write a big book and very difficult to write a small one," surely a salutary doctrine for these days. The truth was illustrated in Bland-Sutton's classic book on tumours, which has gone through many editions. In it he brought into small compass and proper interrelation a crowd of unorganized facts, and vivified the subject for generations of students. He would have nothing to do with dull half-tone illustrations, and insisted on wood-cuts. I still remember the interest and relief with which I read this book, so different from some of the woolly and verbose text-books of its day.

Bland-Sutton's mind can also be studied in his earlier book of 1890, "Evolution and Disease", which broke the new ground of comparative pathology. He wished to indicate that "there is a natural history of disease, as well as of plants and animals". "We shall find conditions which we regard as abnormal in man presenting themselves as normal states in other animals." "There has been an evolution of disease *pari passu* with evolution of animal forms." "I quickly saw that the manifestations of disease were regulated by the same laws which govern physiological processes in general." Such are some of his conclusions, illustrated by a wealth of detailed examples derived from his studies as pathologist to the Zoological Society. A subject of special interest to him was the comparative pathology of the reproductive organs in animals, and in 1892 he received the Jacksonian Prize of the Royal College of Surgeons for a study of diseases of the ovaries and uterine appendages, which probably determined the direction of his surgical activities.

For some years Bland-Sutton was an active member of the old Obstetric Society, in which discussion was at that time conducted with gloves of minimum weight. There is much to be said for frank discussion, but the hand of the dominant seniors was heavy upon their juniors. A young man read before the Society a paper explaining a novel condition of which he had found an example in a hospital museum. Patronizing criticism followed until Bland-Sutton got up. He said : "Some years ago I was a member of a committee appointed to consider this specimen. We could come to no conclusion about it and I said that it should be placed in a museum, and that some day light would be thrown upon it. Gentlemen, that light has come." Such generous feeling for his juniors was habitual with Bland-Sutton, as the writer—for some years his assistant surgeon at the Middlesex Hospital—can testify from personal experience.

Though in youth he must have been a great reader, Bland-Sutton's regard for books was not a very high one, and he always strove for first-hand knowledge of any subject which interested him. His library was kept to an absolute minimum, partly by the incineration of intruders as soon as they had been perused. His interest in general literature was not keen, though Egyptian and Persian archæology fascinated him. The Bible, Nature, Shakespeare, the world of men and women (for he was a great traveller), were his educators, and for his strong personality these sufficed. It was not only in his profile, but in himself also that something Napoleonic could be detected. It showed in his intense industry, his coolness in crisis, in his quick grasp of the essentials of a problem, in the rapid translation of decision into action, and in a certain aloofness of personality. His nature was kindly and generous. Fortune allowed him to enjoy the golden age of Victoria and to exercise for years a splendid hospitality in the replica of a hall which a king of Persia had built for himself. In his consulting room was an Egyptian frieze representing the weighing of the soul after death in the courts of Osiris. It was his reminder to himself of his mortality, and of the ethical standards surviving from his Puritan training.

I cannot conclude without a reference to the mutual devotion which for so many years bound Sir John to Lady Bland-Sutton, who survives him.

W. SAMPSON HANDLEY.

Prof. J. A. MacWilliam, F.R.S.

BY the death on January 13, at the age of seventy-nine years, of Prof. J. A. MacWilliam, the University of Aberdeen and the medical sciences have lost one who by devoted service to his Alma Mater and untiring zeal in scientific investigation had become known to many at home and abroad. He had held the regius chair of physiology at Aberdeen for forty-one years, from 1886 until 1927.

Prof. MacWilliam's chief contribution to scientific medicine was the discovery that the peculiar condition known as fibrillar contraction of the heart consisted of a lack of harmony in contraction and relaxation of the minute bundles of muscle fibres of which the walls of the heart are composed. He showed that fibrillation is not due to interference or destruction of some co-ordinating nerve centre; but that it is brought about by what he described as a "rapid succession of inco-ordinated peristaltic contractions". He also showed clearly the relation of the refractory period to this disturbance. It is not without interest to note that the real significance of his work was not fully recognized until comparatively recent times. The work had its inspiration in the famous school of Ludwig at Leipzig, which, in the eighties of last century, was a Mecca for many of the younger physiologists on both sides of the Atlantic. Bowditch of Harvard, Gaskell of Cambridge, MacWilliam and others were at that time actively engaged in demonstrating those peculiar properties of heart muscle upon which cardiac rhythm depends.

For several years, MacWilliam's indifferent health interfered with intensive original research, and it was not until 1913 that a further series of important papers appeared on the measurement of blood pressure in man. These investigations were the subject of a comprehensive discussion which appeared in *Physiological Reviews* in 1925. There are other publications to which reference might be made, but those mentioned indicate the extent of his work and the high estimate which has been placed upon it. In 1916 MacWilliam was elected a fellow of the Royal Society, an honour which brought satisfaction to many of his colleagues and students.

It is perhaps as teacher and lecturer that MacWilliam will best be remembered. Gifted with a clear and lucid style, he could present, with but the slightest reference to notes, the most difficult aspects of his subject. As a lecturer he had few equals; every lecture was excellently arranged, clearly delivered and full of interest and incident. To those who had the privilege of knowing him intimately, Prof. MacWilliam revealed a new depth and richness of character which made one realize the greatness of his personality. The experience of the years—and they were not without their share of sorrow and suffering—had produced a wonderful combination of philosophical insight and critical scientific judgment.

By his personal qualities, always gracious, never unkindly critical, ever sympathetic, Prof. MacWilliam endeared himself to many generations of Aberdeen students. His charm of manner, his constant kindness and courtesy, won for him the affectionate regard of all who knew him intimately. In the world of science his name has an enduring place; in the hearts of his friends his memory will for long be cherished. E. W. H CRUICKSHANK.

Sir Halley Stewart

SIR HALLEY STEWART, whose death at the advanced age of ninety-nine years occurred on January 26, was a generous supporter of scientific research. One of his outstanding benefactions was the founding of the Halley Stewart Laboratories for Physics Research at Hampstead, which now forms a post-graduate school of the Physics Department of King's College, London. These laboratories were in the first instance put at the disposal of the College in 1932 for the special use of Prof. E. V. Appleton, whose radio researches in the college buildings in the Strand had been greatly hampered by the electrical interference caused by adjacent machinery. The premises in Hampstead, which were formally opened by Lord Rutherford, provided a fully equipped electrical research laboratory as well as a residence above, for the professor of physics. During the years 1932–36, Prof. Appleton and his students were able to continue unhampered their exploration of the properties of the higher atmosphere using radio waves emitted from the roof of King's College and received at Hampstead. Since Prof. Appleton's translation last year to Cambridge, the Halley Stewart Laboratories have been directed by the present Wheatstone professor, Dr. C. D. Ellis, whose researches lie mainly in the field of radioactivity.

WE regret to announce the following deaths:

Prof. Stanley R. Benedict, professor of biochemistry in Cornell University Medical College, on December 21, aged fifty-two years.

Prof. Philip E. Browning, formerly associate professor of chemistry in Yale University, an authority on the rare elements, on January 2, aged seventy years.

News and Views

New Year Honours

THE following names of scientific workers and others associated with scientific work appear in the list of New Year honours conferred by the King, which was published on February 1. *Baron:* Sir Harry McGowan, chairman of Imperial Chemical Industries, Ltd. *Order of Merit:* The Right Hon. H. A. L. Fisher, warden of New College, Oxford, in recognition of his eminent position as an historian and of his services to literature. *K.C.B.:* Mr. H. T. Tizard, rector of the Imperial College of Science and Technology. *Baronet:* Mr. P. Malcolm Stewart, late Commissioner for the Special Areas (England and Wales). *K.C.M.G.:* Mr. F. A. Stockdale, agricultural advisor to the Secretary of State for the Colonies. *D.B.E.:* Lady (Juliet Evangeline) Williams, honorary treasurer, Queen Charlotte's Anæsthetic Fund, and honorary secretary of the Joint Council of Midwifery. *Knights Bachelor:* Dr. J. A. Arkwright, member of the Agricultural Research Council; Prof. J. C. G. Ledingham, director of the Lister Institute, London, professor of bacteriology, University of London; Lieut.-Colonel A. G. Lee, Engineer-in-chief, Post Office Engineering Department, General Post Office; Dr. E. K. Le Fleming, chairman of the Council of the British Medical Association, a member of the General Council of Medical Education and Registration of the United Kingdom; Mr. C. G. Trevor, Indian Forest Service, Inspector-General of Forests, and president of the Forest Research Institute and College, Dehra Dun.

C.B.: Dr. L. D. Barnett, lately keeper of Oriental printed books and manuscripts, British Museum; Mr. F. C. Cook, chief engineer, Roads Department, Ministry of Transport; Dr. M. F. Lindley, comptroller general of patents, designs and trade marks and comptroller of the Industrial Property Department, Board of Trade. *C.S.I.:* Mr. F. Anderson, Indian Service of Engineers, chief engineer and joint secretary to the Government of the United Provinces in the Public Works Department, Irrigation Branch, United Provinces; Mr. T. B. Tate, Indian Service of Engineers, chief engineer and secretary to the Government of the Punjab in the Public Works Department, Irrigation Branch, Punjab. *C.M.G.:* Mr. R. Marrs, principal, Ceylon University College. *C.I.E.:* Mr. C. E. L. Gilbert, Indian Forest Service, chief conservator of forests, Bombay Presidency, Bombay; Dr. D. Penman, chief inspector of mines in India, and lately principal, Indian School of Mines, Dhanbad; Rao Bahadur Tiruvadi Sambasivaiyer Venkataraman, Indian Agricultural Service, sugarcane expert, Imperial Cane Breeding Station, Coimbatore; Mr. H. Pereira, Bombay Forest Service, personal assistant to the chief conservator of forests, Bombay Presidency, Bombay; Major H. C. Phillips, Indian Medical Department, superintendent of the Punjab Vaccine Institute, Lahore, Punjab; Mr. J. H. Smith, principal, Oaklands Farm Institute, and agricultural organizer for Hertfordshire.

History and Significance of the Electron

DR. KARL T. COMPTON, while professor of physics in Princeton University, performed and inspired a great deal of work on the phenomena of the electric discharge in gases, on the emission of electrons from surfaces and on ionization by electron impact. He is now president of the Massachusetts Institute of Technology. His article on "The Electron: its Intellectual and Social Significance" published as a supplement in this issue (p. 229) contains a survey, written in general terms, of the development of our knowledge of the electron since its discovery at the end of last century. The discovery of the electron, and the application of the electron ideas, first to gas discharges, then to radioactivity, spectroscopy and atomic structure, opened a most rapid advance in physical science, leading up to contemporary views of atomic structure and of chemistry. Applied to technical sciences, particularly in the communication industries, the electron has assumed great commercial and social significance.

Prof. C. N. Hinshelwood, F.R.S.

MR. C. N. HINSHELWOOD, who succeeds Prof. Frederick Soddy as Dr. Lee's professor of inorganic and physical chemistry at Oxford, is a leader of physical chemistry in Great Britain. Still in his thirties, he has made a great reputation by his work on gas reactions. He was formerly fellow of Balliol College and University lecturer in chemical dynamics. He is a fellow of Trinity College, a fellow of the Royal Society, an honorary doctor of science of Dublin and a delegate of the Clarendon Press. He is the head of the Balliol and Trinity Colleges Laboratories, and is the first member of this school of physical chemistry to become professor at Oxford. He is a man of wide interests outside his professional work and, in particular, an expert linguist. At Oxford, professorships are attached to particular colleges. In the ordinary way Prof. Hinshelwood should migrate to, and become a fellow of, Exeter College on his appointment. It has happily been arranged, however, that he remain at Trinity College, and in charge of the laboratories there, until an official University institute of physical chemistry be built in the Parks.

Science in the U.S.S.R.

REFERENCES were made in NATURE of January 23 (p. 142), and January 30 (p. 185) to the position with regard to the International Congress of Genetics which was to have been held in Moscow this summer. A request for further information was sent to His Excellency the Russian Ambassador, who has favoured us with a statement on the recent meetings of the Lenin Agricultural Academy (see NATURE, Jan. 30) and on the International Congress of Genetics. Dealing with the latter, the statement is as follows:

"As to the postponement of the Genetics Congress, it is a fact that this was due to requests received by the organisers of the Congress from a number of scientists who wished to have more time for preparation for it. The sole motive for such a postponement was therefore the desire to secure the very best preparation for the Congress and the widest possible participation in its work by scientists of different countries. One thing must be borne in mind in any discussion of the problems of scientific development in the U.S.S.R. The U.S.S.R. is a country of planning. The whole economy of the country, and also the various branches of its cultural and scientific activities are regulated by a definite State plan. Science is planned, not, of course, in the sense that every minute detail of scientific research, etc., is laid down beforehand in a Government Department. That would be ridiculous. But science is planned in the sense that the broad outlines of its development are brought into line with the most urgent requirements of practical life. The prevailing view in the U.S.S.R. is that science must not consider itself a demi-god with the right to choose its own course without any reference to the needs and requirements of the people. On the contrary, the primary object of science is to serve as faithfully as possible the needs of the people, and, indeed, of humanity. Some scientists in foreign countries seem to be inclined to confuse the planning of science, in the above sense, with a lack of scientific freedom. But this is a cardinal error. The planning of science, like planned economy, prevents the waste of human energy and endeavour, and makes it possible to concentrate the greater part of scientific effort on the points of real need of the people and of humanity. The great advantages of such a system are clearly shown by the enormous advance of science in the U.S.S.R. during post-revolutionary years. Indeed, every unbiased observer will testify to the very great prospects for scientific development which exist in the U.S.S.R., such as can be found in scarcely any other country."

The United States Floods

THE catastrophic inundation of the valley of the River Ohio, which was referred to in NATURE of January 30 (p. 185), has since assumed even more alarming proportions and threatens to overwhelm in a comprehensive deluge the whole of the Mississippi Valley from the town of Cairo (Illinois) at the junction with the Ohio River right down to the Gulf of Mexico. The flood waters from the latter river are moving onwards, unchecked and uncontrolled, at the rate of 80–90 miles per twenty-four hours. The extent of country involved can be seen from the accompanying map. At the moment of writing, Cairo is just commencing to receive the crest of the wave, which is expected to culminate in a level of 62 ft. Thence it will pass on through Memphis (Tennessee), Vicksburg and Natchez (Mississippi) to Baton Rouge and New Orleans (Louisiana). In the Ohio Valley there has been left a track of widespread ruin and desolation, with the water still standing 12 ft. deep in the streets of Evansville, just below Louisville. Surveying the disaster at the week-end, the American Red Cross reported 400 people dead, 800,000 homes flooded, more than a million people still homeless and more than a quarter of a million marooned in the upper floors and roofs of their houses or other refuges. The chairman stated with every justification that the American nation is faced with the gravest emergency since the Great War. The material damage is estimated at 400 million dollars (£80,000,000). Not less important is the denudation of the valley, from which some 3,000,000 tons of fertile soil have been swept down-stream by the force of the current.

ORDERS have been issued from Washington to the Army to prepare plans for the evacuation of the entire civilian population within an area extending fifty miles on each side of the Mississippi, in case of a collapse of the levees with which the river banks are topped. Already 60,000 people have moved to higher ground in Arkansas and 30,000 have left their homes in Missouri. Disease and privation have followed on the heels of the flood. A state of quarantine has been declared in Louisville, where typhoid is prevalent, and 200,000 persons have been inoculated. An explanation put forward to account for the magnitude of the disaster is that the Ohio has received as much run-off from rainfall within a fortnight as it usually receives in six months, by reason of the mildness of the season, which has allowed mountain streams to run freely instead of the flow being retarded by the formation of ice and snow, which normally melts slowly during the spring months. Meanwhile, though it is reported that rain has continued to fall heavily in the afflicted area, it is hoped that the worst is past, and that the serious forebodings hitherto entertained will not be realized.

Recent Solar Activity and Radio Fadings

AMONG the recent solar phenomena, now betokening a considerably disturbed sun, may be noted two large groups of sunspots and a smaller one of special interest. Particulars of these groups are as follows:

	Date on Disk	Central Meridian Passage	Latitude	Maximum Area
(1)	January 17–30	January 24·2	19° S.	1500
(2)	January 19–Feb. 1	January 26·1	20° N.	600
(3)	January 24–Feb. 6	January 31·2	11° S.	1500

Areas are expressed in millionths of the sun's visible hemisphere.

Group (1), although of considerable size on January 19, declined rapidly after a few days and by January 27 had shrunk to less than 200 millionths in area. In association with group (2) an extensive bright $H\alpha$ eruption occurred on January 27 between 10^{h} and 12^{h}. This eruption was recorded on hydrogen spectroheliograms taken by Mr. Evershed at his private observatory at Ewhurst, Surrey; at Greenwich it was cloudy at the time. The first spectroheliograms, taken at $10^{h}\,36^{m}$ and $10^{h}\,46^{m}$ U.T. respectively, show a patch of strong $H\alpha$ emission at a position 22° N. and 23° W. of the sun's central meridian; at $10^{h}\,55^{m}$ the eruption was still present, but at $12^{h}\,7^{m}$ when the last spectroheliogram was taken the eruption had almost faded from view. The beginning of the eruption, normally very sudden, may therefore be placed at some minutes earlier than $10^{h}\,36^{m}$, and the ending, usually much less definite, at about $12^{h}\,10^{m}$.

IT is interesting to record that a radio fading on short-wave wireless transmission was reported to have occurred at the same time on January 27 from $10^{h}\,25^{m}$ to $11^{h}\,50^{m}$. A passing comment may be made on the fact that bright solar eruptions, associated with fadings of short-wave radio transmission over daylight channels, occurred at 27-day intervals on December 30 and December 3 last (see NATURE, Dec. 12, p. 1017 and Jan. 9, p. 61). Furthermore, this apparent 27-day sequence is carried back still further by the recorded radio fadings on November 6 and October 9. The requisite international solar data are not yet published to see whether bright solar eruptions were observed at the time of the radio fadings on the last two dates. At the time of going to press, it is reported from the Royal Observatory, Greenwich, that the third group of the above list has increased greatly in size, and on January 31 it was about 2500 millionths of the sun's hemisphere in area. The group is likely to be the largest recorded since 1928.

Recent Crystallography

IN his Friday evening discourse at the Royal Institution on January 29, Sir William Bragg discussed recent work in crystallography. When X-rays were first applied to the determination of crystal structure, the forms examined were naturally those of simple design. As the technique improved, and as insight was gained into the modes of construction of which Nature made the most use, it became possible to attack more difficult examples with success. Quite recently, the X-ray methods have been able to give material assistance in the examination of the complicated bodies which play the leading part in the living organism, such as the proteins. X-rays have the special power of discerning regularities in the arrangement of the atoms and molecules of which substances are built. Until they were applied to this purpose, no one had suspected how usual and fundamental such regularities were. Nature's structures are generally based on the repetition of some unit of pattern. Even a very small crystal is formed of the orderly repetition of some atomic design repeated billions of times: and the minute but ubiquitous proteins of all living organisms possess this ordered arrangement though they are far too small to be seen in the microscope.

THE proteins all have the same basic composition. This again is an instance of the remarkable limitation to a few fundamental and elemental designs which is characteristic of the natural world. Every protein is composed, in the first instance, of a long chain in which two atoms of carbon and one atom of nitrogen form a pattern of three links, repeated throughout the whole length. Pendants of several varieties are attached to this chain, and one protein differs from another in the nature and variety of its pendants. The work of Astbury and others has shown the details of the construction of the proteins which make up the fibre of wool and hair and horn. It appears that in some substances, such as the uncooked white of an egg, the protein chain is coiled up into the form of a ball. Quite recently, Stanley, of the Rockefeller Institute, has been successful in isolating what is almost certainly the virus of the tobacco plant disease, and showing that it is a protein. This is most remarkable since the virus, by some means or other, is capable of multiplying itself. Bernal and his collaborators have shown that it is crystalline, and have used the X-rays to measure the regularities of its construction. It is of enormous size, relatively to the usual molecular dimensions, having a molecular weight of about twenty millions. It is needle-like in form. It has the optical properties of a crystal. This remarkable combination of properties is probably to be found in other forms of disease-producing virus, and the new discovery may well prove to be of the greatest importance.

Germany and the Nobel Prizes

DURING Herr Hitler's speech to the Reichstag in the Kroll Opera House, Berlin, on January 30, it was announced that he had issued a decree forbidding Germans to accept any Nobel Prize in future. This decree has been issued to avoid repetition of "shameful events of the past", which presumably refers to the award of the Nobel Peace Prize last year to Herr von Ossietzky, the German pacifist. The decree has been received with resentment in Sweden; but the Swedish Nobel Committee looks upon it as Germany's loss, for, since 1901 (when the first prize was awarded), nearly one quarter of all the Nobel prizes have been awarded to German citizens, and during the past ten years twelve out of the forty-one

SUPPLEMENT

No. 3510 SATURDAY, FEBRUARY 6, 1937 Vol. 139

THE ELECTRON:
ITS INTELLECTUAL AND SOCIAL SIGNIFICANCE*

By Dr. Karl T. Compton,
President of the Massachusetts Institute of Technology

WITHIN the past five years, centenaries, bicentenaries and tercentenaries have been much in vogue. Every town or institution or event which has claim to distinction has sought the excuse of the calendar to remind the world of its claims to greatness. Thus we have recently celebrated the centenary of Faraday's discovery of the principles of electromagnetism and the bicentenary of Watt's invention of the steam engine—discoveries which have introduced the eras of electricity and of mechanical power. The city of Chicago has sought to tell us that the progress of mankind really began with the founding of that community, and has led us to spend millions of dollars to gain the impression that there is really some causal relationship between Chicago and world progress. In my part of the country, the city of Boston and its suburbs staged a succession of tercentenary celebrations, as proud of their past as Chicago is of its present. Greatest of all was last summer's tercentenary celebration of Harvard University, signalizing the firm basis of intellectual freedom and leadership which is the prime requisite for a free people in a democracy.

Encouraged by the success of the Chicago Century of Progress and the Harvard Tercentenary, I venture to feature my address as signalizing an anniversary of the discovery of the electron. To be sure, it is only one generation old, and a generation is a sufficiently vague unit of time for my purposes. Yet, in spite of its youth, it bids fair to rival Chicago in its contributions to economic progress, and Harvard University in its contributions to the understanding of this world in which we live. So I venture to assert that no institution or community which has used one of these milestones to take stock of its achievements and plot its future course has stronger claims to intellectual significance and practical utility than I will claim for the electron.

The history of science abounds with instances when a new concept or discovery has led to tremendous advances into vast new fields of knowledge and art the very existence of which had hitherto been unsuspected. The discoveries of Galileo, Faraday and Pasteur are such instances. But, to my notion, no such instance has been so dramatic as the discovery of the electron, the tiniest thing in the universe, which within one generation has transformed a stagnant science of physics, a descriptive science of chemistry and a sterile science of astronomy into dynamically developing sciences fraught with intellectual adventure, interrelating interpretations and practical values.

---

* Address of the retiring president of the American Association for the Advancement of Science, delivered at Atlantic City on December 28, 1936.

I take particular pleasure in mentioning these practical values, for even the most unimaginative and short-sighted, hard-headed, 'practical' business man is forced to admit the justification for the pure research—of no preconceived practical use whatsoever in the minds of those who led in its prosecution, and of all degrees of success and significance—which has been directed at the electron. For out of this research have come the following things which all can understand and appreciate : a growing business in manufacture of electronic devices which now amounts to fifty million dollars a year in America alone ; a total business of some hundreds of millions of dollars a year which is made possible by these electronic devices ; innumerable aids to health, safety and convenience ; and an immense advance in our knowledge of the universe in which we live.

THE BACKGROUND

In science, as in human affairs, great events do not occur without a background of development. The electron had an ancestry which can be traced back through the centuries. Its immediate progenitors were the electromagnetic theory of light, spectroscopy and the leakage of electricity through gases. First cousins were X-rays and radioactivity and quantum theory, for, out of a background of long investigation of bewildering and apparently unrelated phenomena, there burst upon the scientific world the X-ray in 1895, radioactivity in 1896 and the electron in 1897—all while investigators in the older fields of heat radiation and thermodynamics were finding those bothersome inconsistencies in these hitherto respectable subjects which led to that unexpected extension of Newtonian mechanics now called quantum mechanics. The concept of the electron, behaving according to the laws of quantum mechanics, is now the basis of most of our interpretation of all that falls under the good old name of natural philosophy.

That only the pioneers of the scientific world were prepared for these discoveries, however, is witnessed by the fact that a standard text-book of chemistry widely used in my student days in 1904 stated that, "Atoms are the indivisible constituents of molecules", and so late as 1911 a prominent physicist warned his colleagues not to be too hasty in accepting these new-fangled ideas.

The existence of electrons had been foreshadowed for a century by the facts of electrolysis, which led Davy and Berzelius to conclude that chemical forces were electrical in nature, and Faraday to conclude that electric charges exist only in multiples of some fundamental unit. For chemical acids and salts, dissolved in water, tend to split up into ions, that is, atoms or groups of atoms which move in an electric field in such directions as to indicate that they carry either positive or negative electric charges. Furthermore, it is found that the amounts of these ions which carry equal amounts of electricity are exactly proportional to the chemical combining weights of the ions. Faraday saw that this fact would be simply explained by assuming that every ion carries a charge proportional to its chemical valency, that is, the valency times a fundamental unit charge. But Faraday could not, from these facts, deduce the size of this unit of charge ; he could only state the ratio of this charge to the mass of the chemical substance with which the charge was associated. Hydrogen, being the lightest of all ions, had of all known substances therefore the largest value of this ratio of charge to mass.

The first real evidence of particles of larger ratio of charge to mass than hydrogen ions came from the field of optics. Ever since Maxwell's equations of electromagnetism had predicted the existence of electromagnetic waves with the velocity of light, and Hertz, seventeen years later, had discovered them experimentally, physicists had felt sure that light must be caused by some sort of oscillations of electricity within atoms. But only the vaguest and most unsatisfactory speculations, such as whirling vortices or pulsating spheres of electricity, had been suggested.

In 1896, however, Zeeman tried the experiment of examining the spectrum of a light source placed in a strong magnetic field, and discovered that the spectrum lines thus became split into components of slightly differing wave-length, and that these components of the light showed characteristic types of polarization depending on the direction in which the light emerged from the magnetic field. Almost at once, in January 1897, Lorentz showed that this experiment proved that light is caused by the oscillation of electric charges, the motions of which are affected by the magnetic field in the manner required to explain Zeeman's experiments. This much was not unexpected, but what was startling was Lorentz's proof that the Zeeman effect could only have been produced by electrified particles whose ratio of charge to mass is nearly two thousand times larger than that of a hydrogen ion, and whose mass is therefore presumably nearly two thousand times lighter than hydrogen.

Almost at once this conclusion was confirmed in a more dramatic and understandable way by J. J. Thomson, the then youthful director of the Cavendish Laboratory. But let me first pick up this thread of the story a little farther back.

DISCOVERY OF THE ELECTRON

All through the eighteen-eighties and early eighteen-nineties a series of most striking and unexpected discoveries followed from investigations of electric arcs, sparks and especially the glowing discharges of electricity at high voltages through glass tubes containing various gases at pressures far below atmospheric pressure. The striking colour effects, mysterious luminous streamers and entirely bizarre behaviour of these discharges made them the most popular, yet most elusive, subject of laboratory research of those days.

It was these phenomena which led Crookes to postulate the existence of a mysterious "fourth state of matter", different from the solid, liquid or gaseous states. (Of course, we now know that Crookes's fourth state is simply the ionized state of matter.) Once, while attempting to photograph the appearance of a discharge at very low gas pressure, Crookes was bothered by the fact that all the photographic plates in the room with his apparatus became fogged, as if light-struck in spite of their opaque wrapping. He avoided the trouble afterwards, however, by keeping his new supply of plates in another room until, one at a time, they were wanted for use. Thus he solved an experimental difficulty, and missed making a great discovery.[2]

At about the same time Röntgen, in Germany, was trying the same experiment, and he too was troubled by the fogging of his photographic plates. But, as the story goes, his laboratory assistant directed his attention to the peculiar fact that these fogged plates, when developed, showed the image of a bunch of keys which had accidentally been lying on top of the box of plates while the electric discharge experiments were in operation. Röntgen immediately looked into this and discovered that the fogging was due to penetrating radiations produced in the discharge tube where the cathode rays struck the target or anode. Thus by accident were X-rays discovered—that type of accident not uncommon in science when an observant experimenter is at work.

While on the subject of accidents, I might digress to tell of another accident which did not happen, also in connexion with X-rays. For more than fifteen years after their discovery, disputes raged as to whether X-rays were radiations, like light but of very short wave-length, or electrically neutral particles of small mass and high speed. It was evident that they were not electrically charged, since their paths were unaffected by electric or magnetic fields. The leading advocate of the neutral particle theory was W. H. Bragg. In 1912, at Princeton, O. W. Richardson tried an experiment to see if X-rays could be refracted by a prism. A positive result would support the wave theory of X-rays. People had tried this with X-rays through glass prisms without success, but Richardson had an idea that an iron prism might be more effective. So he passed X-rays for hours and days through the tapering edge of a Gillette safety razor blade, but without finding any refraction. If he had happened to try the edge of a crystal instead of the edge of the razor blade, he would undoubtedly have discovered the peculiar diffraction of X-rays in passing through crystals, discovered a couple of years later by Laue, Friederich and Knipping and developed by father and son, W. H. and W. L. Bragg, which proved both the wave nature of X-rays and the atomic lattice structure of crystals. If Röntgen's discovery of X-rays was an accident, then I suppose Richardson's failure to discover diffraction of X-rays was a negative accident. I often wonder how many important negative accidents slip past us week by week!

But to get back on the subject of the electron: it was the cathode rays, which produce the X-rays, which finally turned out to be electrons travelling at high speeds. These cathode rays had been observed to shoot out in straight lines from the surfaces of cathodes in rarefied gases through which electric currents were forced by high voltage. Objects which they struck became luminous with fluorescent light, and objects in their paths cast shadows. But their true nature was disclosed when a magnet was placed near the discharge tube, for then their paths were curved in a direction showing that cathode rays were negatively charged. By measuring this curvature produced by a magnetic field of known strength, and making a pretty sure assumption that the kinetic energy of these rays was determined by the voltage applied to the tube, J. J. Thomson in 1897 first showed that cathode rays are negatively charged particles with a ratio of charge to mass nearly two thousand times that of hydrogen. He furthermore showed that these particles are of the same type, as regards ratio of charge to mass, from whatever gas or cathode material they are produced. He therefore announced these particles, which he called 'corpuscles', to be universal constituents of all substances. Thus was the electron discovered.

MASS AND CHARGE OF THE ELECTRON

Quick and fast came experiments of ingenious design to study the electrons more accurately. They were pulled this way and that by electric and magnetic fields. They were caught in miniature metal fly-traps, called Faraday cages, to measure their charge and kinetic energy. They were detected in their paths electrically, or by photographic plates or by fluorescence. Continually refined from that day to this, we now know that an electron has a ratio of charge to mass which is about 1,842 times the similar ratio for a hydrogen atomic ion.

It was also very desirable to know separately the charge and the mass of an electron, and not just the ratio between these quantities. So an even more interesting lot of experiments has been carried on to measure the electron's charge. They were begun in about 1900 by J. J. Thomson and his colleagues, Townsend, H. A. Wilson and C. T. R. Wilson. I think a brief résumé of attempts to measure the electron's charge will throw an interesting sidelight on the versatility of scientific attack on a difficult problem.

The first attempts were by Townsend, by measurements on the motion and electrification of fog produced when electrolytic gas was bubbled into a region of air which was slightly supersaturated with water vapour, but too many uncertainties were involved to make this work convincing. The first accepted results were by J. J. Thomson, who, after an earlier attempt, employed a technique of producing fog under controlled conditions, developed by his colleague, C. T. R. Wilson, whose method was refined further by his pupil, H. A. Wilson.

It had long been known that water droplets of fog do not form in air which is somewhat supersaturated with water vapour unless there are nuclei, like specks of dust, on which the moisture can condense. Later, Townsend found that fog will also condense on ions, and more readily on negative than on positive ions. C. T. R. Wilson designed an apparatus in which dust-free air could be supersaturated with moisture sufficiently to permit condensation of fog droplets on negative but not on positive ions, which were produced by some convenient ionizing agent. So a fog was formed, in which each droplet of water was condensed on a negative ion. Thomson employed this apparatus in the following manner.

Of course, this fog gradually settled downward under the pull of gravity—slowly because the drops were small compared with the viscous resistance of the air through which they fell. It was like the slow settling of dust on the furniture and floor of a room. But the theory of the rate at which spheres move when a force drives them through a viscous medium was already well known, due to Stokes's law. From this law, measurement of the rate of fall of the fog in centimetres per second as measured by a little telescope focused on the top edge of the fog, combined with knowledge of the force of gravity and the viscosity of air, enabled Thomson to calculate the size of the individual fog droplets. Dividing the total amount of water in the fog by the amount in one drop gave him the total number of fog droplets, and therefore the total number of negative ions. H. A. Wilson added the refinement of superposing an electric field on the gravitational field which pulled the drops through the air. Then, as the fog settled to the bottom of the apparatus, it deposited its electric charge, which, altogether, was large enough to be measured with an electrometer. So, dividing this total charge by the number of ions composing it gave, as the charge of one ion, $3{\cdot}4 \times 10^{-10}$ electrostatic units. This was the first real measurement of the charge of an electron, and was the value quoted in the tables of physical constants when I became a graduate student in 1910.

About that time Millikan, who has always had a flair for picking strategically important subjects to which to devote his investigative talents, undertook with his students a revaluation of the electronic charge. Sources of error in the fog method were well recognized: fog droplets were not all the same size, though measurements could only be made on those smallest ones which fell most slowly; also droplets did not remain of constant size, smaller ones tending to evaporate and larger ones to grow; also there were unavoidable convection currents in the air which modified the rate of fall of the fog; and some droplets might contain more than one ion.

Millikan cleverly avoided or minimized these difficulties by using only a single droplet of some relatively non-volatile liquid like oil or mercury. By ionizing the surrounding air in an electric field he could put various electric charges on the drop. Illuminating it by a powerful light and viewing it like a star through a measuring telescope, he could measure its rate of fall under gravity and its rate of rise when pulled upward against gravity by an electric field, and keep repeating these observations for hours. These measurements were so precise that, to keep pace with them, he had to measure the viscosity of air with hitherto unequalled accuracy. When all this was done, he had proved conclusively that all electric charges are integral multiples of a fundamental unit charge, the electron, the value of which he set as $4 \cdot 774 \times 10^{-10}$ electrostatic units—about 40 per cent larger than the earlier estimates and believed by Millikan to be correct within one part in a thousand.

Within the past half-dozen years, however, doubt has been thrown on the estimated accuracy of this value from quite a different direction, in work with X-rays. Originally, X-ray diffraction experiments in crystals proved the geometric arrangement of atoms in the crystals, but did not establish the scale of distances between atoms or the X-ray wave-length. These distances, once the arrangement of atoms was known, were calculated from absolute values of the weights of the atoms, which in turn were derived from electrochemical equivalents and the value of the electronic charge. Thus X-ray wave-lengths, masses of atoms and distances between atoms in crystals all had values dependent on knowledge of the charge of the electron.

Recently, however, A. H. Compton, Bearden and others have succeeded in making measurements of X-ray wave-lengths by diffracting X-rays from a grating ruled with 15,000–30,000 parallel fine lines to the inch, and operating near the angle of grazing incidence. These measurements involve only knowledge of the number of lines per inch on the grating, and the angles of incidence and diffraction of the X-rays—both depending only on measurements of length and capable of high precision. X-ray wave-lengths thus measured were a little different from the earlier accepted values, and this cast doubt on the accuracy of the electron charge value which had been used in the earlier X-ray estimates. The difference was not large, only about one part in two hundred, but it meant either that experiments had not been as accurate as believed or that there was some unrecognized complicating factor.

So Millikan's work has been repeated in various laboratories with refinements, such as the use of a remarkably non-volatile oil for the drop. But the chief error was found to lie in the measurements of the viscosity of air. During the past year Kelletrop, of Uppsala, has thus published a revised 'oil-drop' determination of electronic charge as $4 \cdot 800 \times 10^{-10}$ E.S.U., which is in excellent agreement with the 'X-ray' determinations. Bearden has just presented his own confirmation of this agreement before the American Physical Society.

It is an interesting coincidence that this best value of the charge of the electron is exactly the same as the figure given by Rutherford thirty years ago, though then determined with so much less precision that not much confidence was placed in it, except as to order of magnitude. It was then known that the alpha rays from radium are helium atoms which have lost two electrons and are therefore doubly positively charged. Rutherford caught a lot of these alpha rays in a metal trap, measuring their aggregate electric charge with an electroscope, and counting them by the scintillations which they produced on striking a fluorescent screen or otherwise. Dividing the total charge by the number gave him double the electronic charge, which he thus calculated to be $4 \cdot 8 \times 10^{-10}$ E.S.U. Already knowing the ratio of charge to mass with high precision, this value of the charge enables us to fix the electron's mass as $9 \cdot 051 \times 10^{-28}$ grams.

ELECTROMAGNETIC MASS

When we speak of the mass of an electron, however, we enter a whole new field of ideas. Some years before the discovery of electrons, J. J. Thomson had pointed out that an electrified particle will possess inertia, that is, mass, simply in virtue of its charge alone, irrespective of whether or not it has any mass of the gravitational type which we have been accustomed to think of. This 'electromagnetic' mass comes about from the fact that any mechanical energy which is expended in accelerating an electric charge is transformed into the energy of the magnetic field surrounding the electrified particle in virtue of its motion. In fact, the kinetic energy of a moving electric charge is found to be simply the energy of its magnetic field and depends only on the square of the velocity of the charge, the amount of charge and the geometrical shape of the charge.

Making the simplest possible assumptions about the shape of an electron, such as a solid sphere or a hollow spherical shell of electricity, and assuming all its mass to be of electromagnetic origin, the diameter of an electron was calculated to be of the order of 10^{-13} cm. It must be emphasized, however, that this estimate of size is not, like the charge and mass, a definite measurement, but is simply an estimate based on assumptions, at least one of which is quite uncertain. For while we have both logic and experiment to back up the assumption that all the mass of the electron is of this electromagnetic origin, we must confess to utter ignorance regarding the shape of the electron. Indeed, some facts suggest that it may have different sizes and shapes in different environments, as in the free state or in an orbit of an atom or in the nucleus of an atom. So our estimate of 10^{-13} cm. for the size of an electron is, at best, very crude.

The idea of electromagnetic mass was strongly supported by the fact that measurements of the mass of very fast moving electrons, through measurements of the ratio of charge to mass of beta rays from radium or cathode rays in high-voltage discharge tubes, showed that their mass is not really a constant thing but increases with the speed of the electron. The value of electron mass given above applies, strictly speaking, only to an electron at rest. Practically, however, it is accurate enough for practical purposes for electron speeds below about one tenth the speed of light. At this speed the electron's mass is about half of one per cent larger than if it were at rest. At still higher speeds, the mass increases more and more rapidly, approaching infinite mass as the speed of light is approached.

These facts, experimentally determined, were shown by Abraham to be of the type expected if the entire mass of an electron is of electromagnetic origin, due entirely to its electric charge. It was this argument, which has since received confirmation from other directions, which was the basis of the theory that all mass, that is, all matter, is electrical. However, the simple electromagnetic concepts were not quite adequate to give an accurate quantitative interpretation of these experiments, and it required the additional introduction by Lorentz of the concepts of the special theory of relativity to bring about complete interpretation of the experiments.

THE ELECTRON AND QUANTUM THEORY

Just two things more do we know accurately about the properties of electrons, in addition to their charge and mass. We know that they are also tiny magnets of strength equal to the basic unit of magnetic moment generally called the Bohr magneton. Once the electron had been discovered, it became natural to seek in it also the explanation of magnetic phenomena, since it was only necessary to assume that the electricity of an electron is whirling about an axis, and the electron becomes endowed with the properties of a tiny magnet. Parsons, Webster and others examined the possibilities inherent in various assumed configurations, with interesting results. But it was only with the introduction of the quantum theory for the interpretation of atomic structure and spectra that the magnetic character of the electron has, within the last dozen years, been put on a well-established basis.

The other thing we know is perhaps the most unexpected of all the electron's properties—it behaves like a wave when it collides with other objects. Davisson and Germer discovered this in the Bell Laboratories, while examining the way in which a beam of electrons, incident on a solid surface, was scattered or reflected by it. They found, if the surface were crystalline, that the electrons were scattered just like diffracted X-rays, but that, unlike X-rays, the wave-length of an electron is not fixed but varies inversely as its speed. J. J. Thomson's son, G. P. Thomson, has made very illuminating studies of this phenomenon, which is the inverse of the Compton effect; together they have given physicists two mottoes: "Particles behave like waves and waves behave like particles" and "Here's to the electron: long may she wave". One of the triumphs of the new wave-mechanics (a brand of quantum mechanics) is that it offers a medium of explanation of these strange phenomena. But my subject of the electron is too long to let me attempt a digression on wave mechanics.

SIGNIFICANCE OF THE ELECTRON CONCEPT

With this sketch of the electron itself before us, let us turn to some of the more important directions in which the electron has given us an interpretation of the physical universe generally. Immediately were explained the phenomena of electrolysis and of ionization generally, for ions were simply atoms or groups of atoms which had gained or lost one or more electrons. Primary chemical forces were explained as the electrostatic attraction between atomic groups which, respectively, contained an excess or a deficiency of electrons. (The more refined interpretation of chemical forces within the past half-dozen years, by Pauling and Slater, has been based upon the quantum theory of atomic structure.)

The three types of rays from radioactive substances were interpreted: alpha rays as helium atoms which had lost two electrons; beta rays as electrons; and gamma rays as X-ray-like radiations. In fact, Becquerel showed the magnetic deflection of beta rays in the same year, 1897, that Thomson showed the magnetic deflection of cathode rays and interpreted them as electrons.

For many years two unexplained phenomena had been studied in metals. When highly heated or when illuminated by ultra-violet light, metals had been shown to emit negative electricity. It was the work of but a year, after the discovery of the electron, for J. J. Thomson and his pupils to show that both these phenomena consist in the emission of electrons. But by what mechanisms are they thus emitted? That was a question the study of which has led to most important theoretical and practical consequences.

Richardson, first as a pupil of Thomson and then as a professor at Princeton in the early nineteen hundreds, developed the theory of thermionic emission of electrons, according to which the electrons are evaporated from the surface of a metal at high temperatures by a process very analogous to evaporation of molecules. The electrons are assumed to have the same distribution of kinetic energies that molecules possess at the same temperature in accordance with the principles of kinetic theory. They escape from the surface, if they reach it, with enough energy to take them away in spite of the attraction tending to pull the electron back into the metal. This attraction is expressed in terms of the now famous 'work-function', a sort of latent heat of evaporation of electrons, which is the work that must be done to get an electron clear of the surface. With these simple assumptions, an equation was derived for the rate of emission of electricity as a function of temperature which has stood the test of perhaps as wide a range of experimentation as any other equation of physics, a range of values of more than a million-million fold in current without any detectable departure from the theory, if this is properly applied.

Richardson's measurements of the 'work-functions' of various metals showed that these values run closely parallel with one of the longest known but least understood properties of metals, namely, their contact potential properties. By contact difference of potential is meant the voltage difference between the surfaces of two metals when they are placed in contact. Richardson found that the difference between the 'work-function' of two metals was, within the limits of accuracy of the data, the same as their contact difference of potential. He therefore proposed the theory that the contact potential property of a metal is determined simply by the work necessary to remove an electron from its surface.

As a beginning graduate student under Richardson in 1910, I was given the job of undertaking a test of this theory through experiments on the other electron-emitting phenomenon, the photoelectric effect. Einstein a few years before had proposed his famous photoelectric equation, which was a contribution to physical theory certainly comparable in importance and thus far more useful in its applications than his more impressive and wider publicized general theory of relativity. According to it, an electron in a metal may receive from the incident light an amount of energy proportional to the frequency of the light—to be exact, an energy equal to Planck's constant h times the frequency ν. If it escapes from the metal, it must do an amount of work w to get away, so that its kinetic energy after escape from the metal would be the difference $h\nu - w$. Obviously, by measuring these kinetic energies of electrons liberated from various metals by light of various frequencies, it should be possible to find out if the 'work-functions' w of different metals are indeed related to their contact differences of potential in the manner predicted by Richardson's theory.

In two papers, by me in 1911 and jointly with Richardson in 1912, it was concluded first that the contact differences of potential are related to the 'work-functions' as Richardson had predicted, and secondly that Einstein's photoelectric equation, rather than a rival theory then under discussion, properly described the facts. Practically simultaneously with this second paper, there appeared the report of a similar verification of Einstein's equation by A. L. Hughes, then in England, though lacking the quantitative connexion with contact differences of potential.

This early work was not very accurate, partly because of lack of good vacuum technique for maintaining untarnished surfaces in a vacuum, partly through lack of constant sources of ultraviolet light and partly because the ultra-violet spectrographs used to isolate the various wavelengths of light gave a certain spectral impurity of scattered light of other wave-lengths. These sources of error were recognized but not overcome when Millikan, in 1916, made a striking advance by using doubly purified light or otherwise correcting for the effects of impurity, and secured a verification of Einstein's equation which was far more accurate than the earlier work as regards the value of Planck's constant h. In fact, Millikan's work remains to this day as one of the best determinations of this important constant. In regard to the 'work-function', however, this work of Millikan's was not so successful, for, after having apparently discovered facts at variance with Richardson's interpretation of the equation and its relation to contact potentials, these differences were ultimately found to reside in faults of experimental procedure or interpretation, so that Richardson's interpretation of Einstein's equation still holds.

In both thermionic and photoelectric effects, theoretical refinements have been introduced by the recent quantum mechanics, and great advances made in experimental technique. However, it is fair to say that their interpretations on the electron theory have been among the major achievements of this theory.

CONDUCTION OF METALS

While we are on the subject of electricity in metals, what constitutes the phenomenon of easy flow of electricity that is the distinguishing feature of metals ? J. J. Thomson at once suggested that this must be due to the existence in metals of electrons free from their parent atoms, moving freely, except for collisions, whenever an electric field was applied in the metal. The theory thus worked out was attractive, but it encountered inconsistencies. There was not even any real evidence that electricity in metals was conducted by electrons.

Then along came Tolman with one of his brilliant ideas, skilfully followed by experiment. It had earlier been suggested that, whatever are the carriers of electric current in metals, it should be possible to centrifuge them toward the periphery of a disk if this were rotated very rapidly about its axis. To be more specific, if electrons are free to move in metals and if a wire connects the centre and the periphery of the rotating disk through lightly pressing brush contacts, electrons should be thrown out of the disk at its periphery and pass back into the centre of the disk through the wire. It would be rather analogous to a current of water driven by a centrifugal pump through a pipe circuit. But all attempts to detect such currents proved futile, because the currents produced by the friction of the contact against the periphery were far larger than the currents to be expected from the centrifuging of electrons.

But Tolman devised two methods of giving powerful accelerations to metal conductors in such manner that he was able to measure the feeble electric currents that were produced as the carriers of electricity in the metal were shaken back and forth, and his calculations showed that these currents were indeed of the size to be expected if the current is carried by electrons. This is our direct evidence that electrons carry the electric current in metals. The mechanism by which they do this is now beginning to be disclosed by Slater, on the basis of an application of quantum mechanics and spectroscopic ideas to metals, and again is an example of the refining power of the quantum theory to succeed where older classical theory was gropingly suggestive, but inadequate.

STRUCTURE OF THE ATOM

Now that I come to the most basic of all the phenomena which the electron has been called upon to interpret, I almost lose courage, for the subject is too vast and complex for anything but encyclopædic treatment. I refer to the structure of atoms. Previous to the discovery of the electron, literally nothing was known of the internal structure or composition of atoms. With this discovery, however, it immediately became evident that all atoms contain electrons and an equivalent amount of positive electricity in some form. It was again J. J. Thomson's genius which began the investigation of the inner atom. This was only about twenty-five years ago.

Thomson reasoned that, if X-rays were made to fall on any substance, the electrons in the atoms of the substance would be forced to vibrate back and forth by the powerful alternating electric forces in the X-ray waves. But, in thus vibrating back and forth, these electrons would re-radiate secondary X-rays in all directions. He calculated just what fraction of the original X-ray energy ought to be thus re-radiated by each electron, and then set his pupils to measure just what this fraction was in specific cases. From the experimental results he was thus able to calculate the number of electrons which performed the re-radiation in each case. These results indicated that the number of such acting electrons in each atom was about half the value of the chemical atomic weight of the atom. Thus first were counted the electrons in an atom.

Rutherford and his pupils, aided by the mathematical analysis of Darwin, tackled the problem from a different point of view. They studied the distribution of deflection of alpha particles, shot out of radioactive materials, as these alpha particles traversed thin sheets of solid materials. They found that this distribution was quantitatively what would be expected if the deflections were produced by ordinary electrostatic forces, varying as the square of the distance, between the alpha particle and a very small object containing most of the mass in each atom. They were thus able to show that this small object is not more than one ten-thousandth of the diameter of the atom, that it contained substantially all the mass of the atom and that it carried a positive electric charge equal, in electronic units, to about half the chemical atomic weight of the atom.

Thus arose the concept that the atom is composed of a positive nucleus of small dimensions, surrounded by electrons to the number of about half the atomic weight.

This had scarcely become established when it was brilliantly refined and extended by Moseley, just before he went to his untimely death in the Great War in 1914. Moseley had made a most ingenious study of the spectra of X-rays of a large number of the chemical elements, using a modification of the X-ray spectroscopy technique developed by the Braggs. He found that the square roots of the frequencies of the characteristic X-ray lines were numerically very simply related to the number which gave the place of the element in the periodic table of the elements, so useful to chemists but so entirely without explanation. Thus this number acquired a definite physical significance and is now well known as the 'atomic number'.

For all the elements heavier than hydrogen, this atomic number is about half the atomic weight and, to make a long story short, this atomic number turns out to be exactly the number of electronic units of charge on an atomic nucleus, or the number of electrons in the atom outside the nucleus. At the same time, Moseley's work proved to be one of the greatest advances ever made in the basic interpretive side of chemistry.

Now that the number of electrons in each atom was known, the next step was to wonder how they were arranged, what held them in place and what they were doing in their spare time. Suggestions were not slow in coming. In fact, even before Moseley's work, two rival theories had appeared, one devised by chemist Lewis and extended by Langmuir to explain the directional symmetries of atoms as indicated by their molecular combining forms, and the other devised by physicist Bohr to account for spectra. Gradually the Bohr theory has been developed to include the symmetries of the Lewis-Langmuir theory, so that both may be said to be merged, with many major additions too numerous to mention.

It was Bohr's bold genius to cast off some of the fetters of classical mechanics, which had been fairly well proved inadequate to meet the situation, and to devise a new mechanics frankly to meet the simplest known facts of atomic structure and spectroscopy—the hydrogen atom and the atomic hydrogen spectrum. In doing so, he at one stroke brought into the same picture the quantum theory of radiation, the electronic structure of the atom and the facts of spectroscopy. He had his electron moving in a circular orbit around the nucleus under the regular laws of electrostatic attraction and centrifugal force. But he stipulated that only such orbits were possible in which the angular momentum of the electron was an integral multiple of Planck's constant h divided by 2π. He also stipulated that the electrons should not radiate energy while revolving in their orbits, but only when they jumped from one orbit to another. In this case the frequency of light radiated was equal to the change of energy of the electron between the two orbits, divided by Planck's constant h. With these assumptions, the spectra of hydrogen and of ionized helium were quantitatively explained in their main features, but not in their finer details.

Then came the Great War, and we heard little of atomic structure in the United States. But in Germany, Sommerfeld was extending Bohr's ideas in most interesting ways. He showed that, by considering elliptic as well as circular orbits, and taking account of the variation of the electron's mass with speed, the fine details as well as the main features in the spectra of hydrogen and ionized helium were accurately explained. He also showed how the theory could be extended to deal with atoms where there were many electrons moving in orbits. He showed that these additional concepts were in the right direction to explain the more complicated spectra both in the visible and in the X-ray regions.

SPECTRAL LINES

When this new work first was known in America, it started the most feverish and earnest scientific activity that the country has ever known, which is still in progress with undiminished zeal and with increasing productive effectiveness. I well remember when the first copy of Sommerfeld's "Atombau und Spectrallinen" came to America in the possession of Prof. P. W. Bridgman. Until later copies arrived, he knew no peace and enjoyed no privacy, for he was besieged by friends wanting to read the book—which he would not allow to go out of his possession. I recall, too, the sudden popularity of the only two or three men in America who knew what a spectral series was. Heretofore, practically our only interest in spectra had been in the culinary variety of spectroscopy used by chemists in identifying chemical elements. No interpretive quality to speak of had hitherto been attached to the peculiar numerical regularities which had been discovered in the vibration frequencies of groups of spectrum lines.

I recall, too, the dismay with which we found only a handful of mathematical physicists versed in the analytical dynamics underlying the new atomic structure theories. In the summer of 1921, having been taught by one of these few mathematical physicists, I went to the University of Michigan to lecture on Sommerfeld's theory, and found there also F. A. Saunders, invited to impart his knowledge of spectrum series. In the winter of 1926, Born and Jordan having just announced a new development in quantum mechanics, I found more than twenty Americans in Göttingen at this fount of quantum wisdom. A year later they were at Zurich, with Schrödinger. A couple of years later, Heisenberg at Leipzig and then Dirac at Cambridge held the Elijah mantle of quantum theory. In America, contributions are coming rapidly, particularly in the fields of application to chemical interpretations, metals and other complex situations.

From all this has come the situation which permitted Dirac, a few years ago, to write: "The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the exact application of these laws leads to equations much too complicated to be soluble". But if any ambitious young scientist be discouraged lest there be little left to do, let him consider the unexplored atomic nucleus, or the fact that every attempt to apply these laws, which look so satisfactory to us now, discloses new realms of knowledge still unexplored.

Time forbids mention of the most interesting work which was done to check and extend the theories of atomic structure, through direct measurement of the energy states of atoms and molecules by carefully controlled bombardment of these molecules by electrons. Begun by Franck and Hertz in Germany, much of this work was done in America by Foote and Mohler at the Bureau of Standards, by my students at Princeton and by Tate's group at Minnesota, all since 1920.

Before leaving the interpretive triumphs of the electron, however, I cannot refrain from jumping from the atom to the universe, to the interpretation of conditions on the stars. Spectra of stars had long been known, and these were interpreted as indicating that some stars consist principally of hydrogen, others of helium and others of many chemical elements like our sun. But in 1922, a young Indian physicist, Meghnad Saha, first applied atomic structure theory and knowledge of ionizing potentials to the sun and stars. He considered ionization in the hot vapours of the stars to be like a chemical dissociation produced by heat, in which the products of dissociation are electrons and the positive ionic residues of the atoms, and in which the heats of dissociation are given by the ionizing potentials of the atoms. In this way was developed a rational quantitative interpretation of stellar spectra which has thrown enormous light on the problem of conditions of temperature, pressure and condition of the chemical elements in stars. Russell in America and Milne in England have ably applied and extended this theory.

The Electron in Industry

Finally, I come to the last phase of my subject, the social significance of the electron. By this I mean, of course, its useful applications. The first of these was Edison's invention of a thermionic rectifier, based on his discovery that negative electricity would flow across a vacuum from a hot filament to an adjacent electrode, but would not flow in the opposite direction. This was some years before the electron was discovered as the responsible agent in this phenomenon. But within a few years after the discovery of the electron, Fleming had shown that this same device will operate to rectify radio wave impulses, and thus permit their detection with a sensitive direct-current instrument. From this was patented the Fleming valve.

Once the basic character of thermionic emission was understood, and spurred on by the opportunities opening up in the radio field, new inventions, improvements and applications of thermionic devices came rapidly. Of major importance was the three-electrode tube amplifier of De Forest. Industrial research laboratories in the communications and electric manufacturing business took the lead in developing techniques and in penetrating scientific exploration. Noteworthy were the vacuum techniques and the monomolecular layers of activating materials developed by Langmuir and the high-vacuum thermionic X-ray tube of Coolidge. In the Bell Laboratories, oxide-coated filament tubes of good performance were developed and applied particularly to use in long-distance telephony. Let me give just two illustrations of the marvellous powers of some of these instruments.

It has been calculated that the energy of a trans-Atlantic radio signal caught by the receiving station in Newfoundland comes in at about the rate required to lift a fly seven inches in a year!

What is the largest number that has any physical significance? This is impossible to answer, being largely a matter of definition. But one common answer to this is 10^{110}, or one followed by 110 ciphers. This is about the number of electrons (the smallest things known) which would be required to fill up the universe to the greatest distances discovered by astronomy, if the electrons could be imagined to be closely packed side by side to fill up this whole space. Yet this number, large as it is, is very small indeed compared with the aggregate factor by which the energy of a voice striking a telephone transmitter in San Francisco is amplified by electronic tubes in the process of a long-distance telephone conversation to London. This amplification factor is about 10^{256}, or unity followed by 256 ciphers. If the universe were multiplied in size by the number of times it is larger than an electron, it could still not hold as many electrons as the number of this telephone amplification factor!

Then, mostly within ten years or so, has come an active introduction of thermionic devices which are not highly evacuated, but operate with supplementary action of intense ionization of the gas in the tube. First of these were the low-voltage arc rectifiers, like the tungar. Most interesting and versatile are the thyratrons, which permit easy control of powerful currents and machinery, and give a new means of converting alternating into direct current, or vice versa. In this group also are some of the new types of lamps, of high efficiency or special colour.

Not so striking, but equally interesting, have been the useful applications of the photoelectric effect. First was the use of sensitive photoelectric cells to replace the eye or photographic plate in astronomical telescopes. Then came sunshine meters, devices to open doors or count people or sort merchandise automatically, or to register the speed and licence number of the unwary autoist. Most important thus far are the current-producing mechanisms in the sound-movie apparatus and in television equipment.

While, commercially, radio, sound movies and long-distance telephony are at present of greatest importance, of no less importance, especially to us as scientists, are the marvellous tools which have been put into our hands for further research in practically every field of science, from physics and chemistry to psychology and criminology.

So we see how, within one generation, the electron has been discovered and examined, with its aid our intellectual outlook upon the universe has expanded in content and simplified in basic concept, and in its use mankind has the most versatile tool ever utilized. The end of the story is far from told. Every fact or relationship of the electron appears fuzzy with uncertainties when closely examined, for it can truly be said that every discovery discloses a dozen new problems. The field of practical and commercial uses of electronic devices is certainly still largely in its early stages of exploration.

This story illustrates in vivid manner a number of characteristics of scientific work, some of which I shall simply enumerate: (1) progress comes by spurts of advance as some big new idea opens up new territory, alternating with periods of consolidation; (2) progress comes not by revolution or discarding of past knowledge and experience, but is built upon past experience and is its natural extension once the vision from new vantage points is secured; (3) there is nothing so practical in its values as accurate knowledge, and the pursuit of such knowledge has been most successful when not fettered with the initial demand that it be directed toward practical ends

I would not give the impression that it is only the electron which has given new life to modern physical science. A story of similar interest could be built around the new concepts of radiation and atomic energy as expressed in the quantum theory, or about the electron's big brother, the proton, or his rather nondescript cousin, the neutron. In the atomic nucleus is a field of further exploration of enormous promise, now only beginning to be opened up by use of radioactive materials, cyclatrons and high-voltage generators.

Although these things have happened very recently, no one has better described the process and intellectual value of this type of scientific research than did Aristotle in the quotation which is inscribed in Greek on the façade of the National Academy of Sciences building in Washington: "The search for truth is in one way hard and in another easy, for it is evident that no one can master it fully nor miss it wholly. But each adds a little to our knowledge of Nature, and from all the facts assembled there arises a certain grandeur."

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

recipients of Nobel prizes for physics, chemistry and medicine (more than one quarter) have passed to Germans. Herr Hitler has decreed the creation of three German National Prizes of 100,000 marks (£8,300) each, to be awarded annually to Germans distinguished in art and science.

Gold Medal of the International Faculty of Sciences

At the dinner following the annual conference of the International Faculty of Sciences applied to Human Progress, held in London on January 30, the Faculty's Gold Medal was presented to Mr. John Logie Baird, inventor of the Televisor, and managing director of Baird Television, Ltd. The chairman, Dr. Joseph S. Bridges, said the presentation was made in recognition of Mr. Baird's outstanding contributions to the science of television. In acknowledging the presentation, Mr. Baird indicated the progress that had been made since he first, in 1925, secured a television image with distinct definition. While the high cost of the apparatus at present is a drawback to its wide use among amateurs, he looked forward to a substantial reduction in the near future. Great Britain, he said, definitely leads in the science of television and is the only country in the world which has a television service. Among other speakers, Dr. L. E. C. Hughes commented on the necessity of scientific workers in all branches co-operating more closely to ensure that the achievements are properly applied to the requirements of human progress, and indicated the value of the International Faculty of Sciences in bringing into close touch such workers in all the countries of the world. Prof. B. W. Holman, replying on behalf of "The World's Scientific Workers", stressed the necessity for the social sciences being developed to keep pace with other sciences, so that the achievements of the research workers could be applied in accordance with the objectives of the Faculty, namely, human progress.

Aboriginal Tribes of the Malay Peninsula

While of the aboriginal tribes of the Malay Peninsula the Sakai, the Semang and the Jakun, though by no means well known, have been the subject of careful investigation by a number of observers, the Temiar, a hill people of Perak, are virtually untouched in an anthropological sense. Yet they number nearly one half of the aboriginal population of 25,000. They have, however, been made the subject of a considerable study by Mr. H. D. Noone of the Perak State Museum, who has given some years to the investigation of their culture, their ethnic affinities, and their language, which is said to belong to the Austro-Asiatic group, and to show Indo-Chinese affinities. A preliminary outline of Mr. Noone's results in *The Observer* of January 24 is cabled from Singapore, where a number of the tribe are staying at present for the purpose of a record of their speech. It is there stated that Mr. Noone finds that the Temiar show traces of negritic influence and also an Australoid type, akin to the Vedda, but that, essentially a hill tribe, they link up with the hill stocks of Sumatra and other parts of south-east Asia. They are lighter skinned than the Sakai and belong to a higher order of intelligence and culture. They build communal long-houses instead of the rude shelters of the Sakai, use the bow, and hunt with the blow-pipe. Their religion is animistic. For driving out the spirits of disease, they make use of the religious dance, in which the medicine man is an important figure. These dances are performed in the event of an epidemic, the dancers becoming 'possessed' by a tiger spirit. Eventually they fall into a state of trance, which sometimes ends in complete rigidity.

Tracks for Cyclists

The recent Ministry of Transport accident inquiry proves that, notwithstanding the increase in the number of motor-cars, the casualties among motorists are decreasing. On the other hand, casualties to cyclists are increasing at an even greater rate than we might expect from the growth of the cycling habit. According to a paper read at the National Safety Congress, fatal accidents to pedal cyclists during the seven years 1928–34 had increased no less than 122 per cent. In *Roads and Road Construction* for January 1, it is suggested that the best way to check increase of these accidents would be to copy some of our Continental neighbours and increase largely the number of special cycle tracks available. In Germany there are already about 1,100 miles of track, about two thirds of which is State maintained. According to a recent statement, the decrease which has occurred in recent years in cycling fatalities in Germany can be attributed directly to the making of these tracks. The German authorities are aiming at the provision of no less than 24,000 miles of track. The opposition that cyclists' touring clubs make to special tracks seems to arise from a fear lest these tracks be made not wide enough, so that they will have to travel at the most two abreast, instead of as at present three or four or even more abreast. In the interest of the general safety, it is probable that the privilege of riding three or more abreast will soon be curtailed by law. In many places cycle tracks, like public footpaths, could be built without fences, and probably a large mileage of existing 'green roads' could be utilized. If a number of special tracks were constructed every year, the annual cost need not be large. They would add safety, health and enjoyment to the weekly tours of many cyclists who at present have to pass through main roads crowded by rapidly moving vehicles and sometimes in an atmosphere full of noxious vapours.

Road Lighting in the United States

In *World Power* of November some interesting statistics are given, relating to road accidents, which illustrate the responsibility of bad or non-existent lighting for road deaths and injuries. On the Mount Vernon Highway, near Washington, there were 2·87 accidents per million vehicles per mile, between July 1 and December 1, 1932. When lighting was suspended during the depression, the number of accidents increased to 7·02 over the same period per million vehicles per mile—an increase of 250 per cent.

In New Jersey at present, the night-time accident rates on three unlighted main roads carrying dense traffic are 270 per cent more than the day-time rates. Another striking figure is that more than half the 36,400 people killed by motor-cars in 1935 were injured during the hours of darkness, although the traffic volume was certainly not more than one third that during the day-time. It is concluded that it is not surprising that American engineers are alarmed when they see that New York State, for example, makes an annual expenditure of about twenty-two million dollars in getting rid of railway, street and highway crossings, and yet does little towards the illumination of roads at night. The total number of preventable accidents in 1934 due to railway crossings was 151.

Merseyside Fauna and Flora

The Liverpool Naturalists' Field Club has recently issued volumes of *Proceedings* covering its activities for 1934 and 1935. This brings its number of annual *Proceedings* since its inception in 1860 to seventy-five, a noteworthy accomplishment, for they provide a valuable reference on the changing fauna and flora of the industrial north-west of England. The two latest volumes consist largely of the Ornithological Section report by Eric Hardy, who has built up within the Society the largest organized bird study group in the area. This includes bird-census counts over special areas, organized surveys of bird-calls at dawn and dusk, and statistics of migration and bird-ringing, nesting and rookery counts, etc. The Ornithological Section, states the Committee Report, is now organized independently of, but connected with, the general Field Club. The *Proceedings* also include Mr. W. A. Makinson's presidential addresses for the two years: "The Joys of a Nature Lover" and "Trees and their Service to Man". Reference is made to the discovery, in the Field Club library, of proof that the Society's first president and founder, the Rev. H. H. Higgins, visited the convent at Sinai and examined the famous "Codex Sinaiticus" previous to the examination by the collector Tischendorf. Having traced the journals of this Sinai visit, it is hoped to publish them.

The Scripps Institution of Oceanography

The August issue of the *Collecting Net* (**11**, No. 5) contains an article entitled "Biological Research at the Scripps Institution of Oceanography" by Dr. Claude E. ZoBell. It is announced that Dr. T. Wayland Vaughan is retiring from the University of California, his successor being Dr. Harald U. Sverdrup. During Dr. Vaughan's administration, the Scripps Institute of Oceanography has expanded enormously, and since his appointment as director in 1924 he has gradually developed an extensive research programme in biological oceanography with workers in all subjects connected with it. Among the many great improvements an important one is the growth of the library, which now contains more than 14,600 volumes, 1,100 charts and 30,000 pamphlets. Dr. Vaughan has contributed to the Institution his own personal collection of 1,800 volumes and 6,000 reprints of relevant literature besides numerous periodicals.

Physics Research at Osaka University

Vol. 3 of the "Collected Papers in Physics" from Osaka University consists of thirteen copies of papers which have appeared in the Report of Radio Research in Japan, the *Proceedings of the Physico-Mathematical Society of Japan*, the *Japanese Journal of Physics* and the *Proceedings of the Institute of Radio Engineers of the United States*, between June 1935 and March 1936. They cover subjects such as atomic bombardment, short-wave production, modulation of oscillators, polar molecules, electron diffraction, neutrons and protons and dynatrons. The volume extends to about 125 pages, and is produced by wiring together the separate copies of the papers, with a title page and table of contents, the size of the page being 19 cm. by 26 cm. The original covers of the papers are retained. This inexpensive method of issuing collected papers from periodicals with pages of the same size seems worthy of extension.

Misunderstanding and Misprint

A correspondent has sent us a copy of a programme for 1936–37 of a science society of a university, which contains two amusing misprints. The title of a paper to be contributed by a member of the zoological department of the university was sent in as "Life History of the Ling Cod". The secretary appears not to have recognized "ling" as a food fish of the cod family, so he altered the word to "living". The printers put the finishing touch upon the title by changing the last word also, so that the title appears as "Life History of the Living God", which must surely represent the most ambitious subject of a paper by a zoologist ever announced.

The Influenza Epidemic

The Ministry of Health reports that during the week ending January 16 the number of deaths ascribed to influenza in the 122 great towns of England and Wales was 1,100, as compared with 768 in the previous week. The number of notifications of pneumonia in England and Wales was 2,823 as against 2,338 in the previous week. A considerable increase of influenzal cases has occurred in most of the naval and military commands; but the epidemic appears to be declining in certain parts of the south. The age distribution of deaths is somewhat reassuring, as it is not the type usually met with in severe epidemics. According to Science Service bulletins, a wave of influenza is passing over the United States.

Parkes Memorial Prize

Major E. F. W. Mackenzie, R.A.M.C., has been awarded the Parkes Memorial Prize for 1936 for his investigations into the ammonia-chlorine process of water purification in the field, coupled with research carried out by him in connexion with food supplies in India. The Parkes Memorial Prize is awarded annually to the officer who is considered by the committee to have done most to promote the advancement of naval or military hygiene by professional work of outstanding merit, and is open to medical officers of the Royal Navy, the Army and the Indian Army, with the exception of the professors and assistant professors of the Royal Navy Medical College at Greenwich and the Royal Army Medical College during their term of office.

Studies in Ancient Indian History and Geography

REGULATIONS have now been framed for the work of the Trust founded by the generosity of Dr. Bimila Churn Law, of Calcutta. The funds of the Trust will be used to facilitate the publication of original contributions to the literature on Buddhism, Jainism and the ancient history and geography of India, down to the end of the thirteenth century A.D. The Trust will be administered by the Royal Asiatic Society. Applications for assistance under the terms of the Trust for the period January 1, 1937–December 31, 1938, should be addressed to the Secretary of the Society, 74 Grosvenor Street, S.W.1.

Science and Society

THE Association of Scientific Workers has organized a series of five public lectures under the general title "Science and Society", to be given at University College, London, on successive Wednesdays, beginning February 17. The lectures cover a wide range of topics, and the whole series should prove of unusual interest to scientific workers. Prof. J. B. S. Haldane will talk on "Facts and Theories concerning Human Race Differences" on February 17, and the chairman on this occasion will be Sir F. Gowland Hopkins. On the following Wednesdays, the lecturers will be A. L. Bacharach on "Nutrition and Society", Prof. H. Levy on "The Socialization of Mathematics", Prof. P. M. S. Blackett, on "Physics" and Prof. Lancelot Hogben on "The Social Background of Science". This is the first of an annual series of lectures on the general implications of science which the Association hopes to arrange. Further information and tickets (1s. for each lecture, 4s. for course of five) can be obtained from the Assistant Secretary, Association of Scientific Workers, Kelvin House, 28 Hogarth Road, S.W.5.

Checking the Michelson-Morley Experiment

THE following cablegram has been received from Prof. W. B. Cartmel, of the University of Montreal: " 'A Simple Means of Checking the Michelson-Morley Experiment'. In a letter under the above title which appeared in NATURE of January 16, I reported experiments in which I found a large fringe-shift with a small interferometer having one arm inclined at an angle of 45° and the other arm level. Unfortunately, on continuing my experiments with improved apparatus, this fringe-shift disappeared altogether, so that we get the same result with one arm inclined and one arm level as we do with both arms level, the effect previously reported being apparently spurious."

Announcements

H.R.H. THE DUKE OF GLOUCESTER has accepted the invitation to become president of the British Empire Cancer Campaign. His Majesty the King, when Duke of York, was president of the Campaign from 1924 until his accession to the throne.

THE Council of the Physical Society has awarded the fourteenth Duddell Medal to Prof. W. G. Cady, of the Wesleyan University, Middletown, Connecticut, U.S.A.

MR. COLIN BEVAN REES has been awarded the Foyle Prize at the University College of South Wales for his essay on "Can Science make a Positive Contribution to the Elimination of Armed Conflict?"

DR. LOUIS VERVAECK, director of the service of criminal anthropology in Belgium, has been awarded the Cesare Lombroso prize for criminal anthropology.

MCGILL UNIVERSITY, Montreal, has recently received a gift of 17,000 dollars from the Rockefeller Foundation to cover the expenses of a three-year programme of research in genetics and experimental cytology.

APPLICATIONS for grants from the Ella Sachs Plotz Foundation for 1937–38 must be made before May 1. For the present, researches will be favoured that are directed towards the solution of problems in medicine and surgery or in branches of science bearing on medicine and surgery. Further information can be obtained from Dr. Joseph C. Aub, Collis P. Huntington Memorial Hospital, 695 Huntington Avenue, Boston, Massachusetts, U.S.A.

THE Trustees of the Lady Tata Memorial Fund invite applications for grants and scholarships for research in diseases of the blood, with special reference to leukæmia, in the academic year beginning on October 1, 1937. The grants and scholarships are open to workers of any nationality. Applications must be submitted before March 31, and the awards will be made by the Trustees in June. Further particulars and forms of application may be obtained from the Secretary of the Scientific Advisory Committee, 138 Bedford Court Mansions, London, W.C.1.

ATTENTION may be directed to catalogue No. 42 of Messrs. E. P. Goldschmidt and Co., 45 Old Bond Street, W.1, on navigation, geography, travels and shipbuilding. The catalogue, which is illustrated with several reproductions of old maps, contains many old and rare items including Amman's "Die grosse Allegorie auf den Handel", 1622; Belleforest's "Cosmographie Universelle", 1575; Honter's "Rudimenta cosmographica", 1542, of which very few copies are known; a hitherto unknown first map of Japan, 1586; and Kepler's "Tabulae Rudolphinae", 1627–30, containing his rare world map, which Nordenskjöld believed to be the earliest map showing any indication of the Australian coast line.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 252.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Magnetic Effects associated with Bright Solar Eruptions and Radio Fade-Outs

THE association of certain disturbances of the earth's magnetic field with bright hydrogen eruptions in the neighbourhood of sunspots, first indicated by Prof. Young, led to the conclusion that the solar effect was propagated to the earth with the velocity of light. Fresh impetus has been given these investigations by the observation of extensive radio fade-outs reported by Dellinger[1], at whose request special spectroheliograms were made at the Mount Wilson Observatory, Carnegie Institution of Washington, to investigate possible correlations[2]. A notable fade-out, a marked magnetic and earth-current disturbance, and an unusually bright hydrogen eruption on the sun, all occurring simultaneously, were observed from 16^{h} 45^{m} to 17^{h} 03^{m}, G.M.T., on April 8, 1936, at the Huancayo (Peru) Magnetic Observatory of the Department of Terrestrial Magnetism, Carnegie Institution of Washington[3] and elsewhere. Since then, two other pronounced similar occurrences, one on August 25 and another on November 6, have been reported from the Observatory[4,5], and many instances of a less conspicuous nature have occurred[6].

The characteristic features of these phenomena as revealed so far are a marked increase in intensity of the $H\alpha$ line in the region of a sunspot, cessation of radio reflections from the ionosphere, in particular for the higher frequencies, and in equatorial regions an increase in the horizontal component of the earth's magnetic field, and increases in the electric currents flowing in the earth's crust such as would be induced by the magnetic changes. All the effects, as above noted, begin quite sharply at apparently the same time and end coincidently after a time-interval of the order of 45 minutes. Conditions after the disturbances appear to be normal. The terrestrial effects apparently are confined to the daylight portions of the earth.

The disturbances of the earth's magnetism which accompany these solar outbursts are distinct from the perturbations associated with magnetic storms—the latter are evident at all parts of the earth, while the strong magnetic effects recorded at Huancayo during the outburst of April 8 could not be discerned at the Carnegie Institution's Watheroo Magnetic Observatory, Western Australia, 169° west of Huancayo. Furthermore, both immediately before and immediately after the three notable outbursts mentioned, the earth's field was comparatively free of perturbations, while the perturbations of magnetic storms usually persist for several days; it is not to be implied, however, that the phenomena cannot or do not occur while a magnetic storm is in progress.

The nature of the mechanism which produces the magnetic effects may be surmised from the meagre data already in hand. The disturbance of August 25, for example, may be attributed to a sheet of current in the ionosphere flowing eastward over Huancayo and northward over Cheltenham (U.S.A.) with densities of 60 and 30 amp. per km. width of the current-sheet at the two places, accompanied by corresponding oppositely directed currents inside the earth[4]. In direction and magnitude this current approximates that assumed to produce the ordinary diurnal variations of terrestrial magnetism. Thus the magnetic effects may be ascribed to an increase of ionization, produced by radiation of shorter wave-length than visible light, accompanying the increase of $H\alpha$ intensity, causing an increase in the currents then flowing in the region of the ionosphere affected. The diurnal-variation currents are believed to flow in the lower, short free-path region of the ionosphere.

This hypothesis is consistent with the obvious explanation of the radio fade-outs—that they are due to increased ionization in the short free-path region where frequent collision causes large absorption of the radiated energy. Further, the rapid return to normal conditions, practically coincident with the cessation of the visible solar radiation, also indicates that the effect occurs in the short free-path region where recombination is very high.

An intensive investigation of these phenomena, designed to test this hypothesis and incidentally to clarify concepts of the diurnal variation of terrestrial magnetism and processes of ionization and recombination in the ionosphere, is under way at the Department of Terrestrial Magnetism.

Rainfall and Moon Phases in the Tropics

ON the low-lying east bank of the Demerara River, about eight miles from its mouth, is situate Diamond Plantation, the largest sugar factory in British Guiana, located approximately at 6° 42′ N. and 58° 10′ W. Preserved at Diamond is a valuable record of the daily rainfall for the past forty-six years. Through the courtesy of the Plantation authorities, I have been able to secure a copy of the register.

So many farmers and planters in the West Indies and British Guiana have faith in the new moon or the full moon bringing rain, that it seemed of value to determine, from the Diamond data, what factual foundation there is for the belief.

Popular belief does not definitely fix the fall of rain for the actual date of the new or full moon, but for some time near the date. Thus one frequently overhears such remarks as: "It will be new moon to-morrow and we should get some rain to-night or to-morrow", or "The moon is full to-night so we may get some rain to-night or to-morrow". It was therefore decided to compare the average rainfall for:

(*a*) The three-day period made up of the day before new moon, the new moon day and the day after new moon;

(*b*) The three-day period immediately preceding (*a*);

(*c*) The three-day period immediately following (*a*);

(*d*) The three-day period made up of the day before full moon, the full moon day and day following the full moon;

(*e*) The three-day period immediately preceding (*d*);

(*f*) The three-day period immediately following (*d*).

This was done for the year as a whole and for the dry seasons only, since it might be argued that it is only during the latter that farmers are worried about rain and trouble to note the supposed relationship between precipitation and moon phases. At Diamond the weekly rainfall averages less than two inches from the week ending January 21 to that ending April 29, and again from the week ending August 12 to that ending November 25. These periods were taken as constituting the dry seasons. During the rest of the year the rainfall averages more than two inches per week.

Comparison of Average Rainfall (1914–34) in Inches at New and Full Moon with Rainfall Prior and After, at Diamond, E.B., Demerara, British Guiana.

	New Moon			Full Moon		
	3 Days prior (*b*)	3 Days at (*a*)	3 Days after (*c*)	3 Days prior (*e*)	3 Days at (*d*)	3 Days after (*f*)
Year.	0·81 ± 0 06	0·82 ± 0 07	0·78 ± 0 07	0·85 ± 0 08	0·74 ± 0·06	0·93 ± 0 09
Dry Season	0·50 ± 0·06	0·51 ± 0 07	0 51 ± 0·08	0·48 ± 0·07	0·50 ± 0·07	0.62 ± 0 10

The results obtained for 259 new and 261 full moons (1914–1934), for the whole year, and for 147 new and 146 full moons, for the dry seasons, are set out in the accompanying table.

The differences between the means are as follows:

	Whole Year	Dry Season
a and *b*	0·01 ± 0·092	0·01 ± 0 092
a ,, *c*	0·04 ± 0·099	0·00 ± 0 106
d ,, *e*	0·11 ± 0·100	0·02 ± 0·099
d ,, *f*	0 19 ± 0·108	0·12 ± 0·122
a ,, *d*	0 08 ± 0·092	0 01 ± 0·099

It will be seen that none of the differences is significant and that there is no support whatever for the belief that there is likely to be more rain at the new or full moon than during the days just before or just after these phases. It is of interest to note, too, that the average rainfalls for the new moon and full moon periods are very similar.

Another Double Star Process giving Very Fast Particles

IN a recent letter[1] I pointed out that in order to explain the energies found in cosmic radiation it is necessary to introduce only one hypothesis: that the components of the double stars are magnetic dipoles (as the earth and the sun). Then a rotating double star acts as a cyclotron. A more detailed calculation[2] shows that energies of 10^{10} or 10^{11} (perhaps 10^{12}) electron volts are attainable, but as the accelerating process is rather complicated it seems unlikely that it can be responsible for the total intensity of cosmic radiation. Therefore it may be of interest to point out that there are also other—and more simple—double star processes which are able to give high-energy particles.

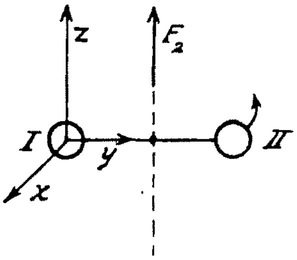

Fig. 1.

Let us assume that the two components I and II of a double star are parallel magnetic dipoles with the same moment (*a*). The star II rotates around I in the *x y* plane with the constant angular velocity ω_0 and at the constant distance R_0 from I. If we follow the symmetry line parallel to the *z*-axis, the resulting magnetic field is always parallel to it. This means that charged particles can move freely in this direction. The field along this line is composed of the field H_1 from the component I supposed to be in rest, and the field H_2 from the component II which moves with the velocity $R_0\omega_0$. Now a moving magnetic field gives rise to an electric field. In our case the electric field component along the symmetry line is

$$F_z = \frac{R_0\omega_0}{c} H_{2y},$$

where H_{2y} is the *y*-component of the magnetic field from II and *c* the velocity of light. The energy *V* (in electron volts) gained by a charged particle which has travelled from the *x y*-plane to infinity is

$$V = 300\int_0^\infty F_z dz,$$

and as $H_{2y} = \frac{3}{2} aR_0 z \left[z^2 + \left(\frac{R_0}{2}\right)^2\right]^{-5/2}$, we find

$$V = 1{,}200\,\frac{a\omega_0}{cR_0}.$$

If the period of the double star is 1 day, R_0 is 7×10^{11} cm. (ten times the radius of our sun) and

a is $2{\cdot}5 \times 10^{34}$ gauss cm.^{3} (five times the magnetic moment of the sun), we have

$$V = 10^{11} \text{ electron volts.}$$

If the orientation of the magnetic moments in relation to the rotation is the same as in our solar system, the accelerated particles have a positive charge.

Luminous Efficiency of Rays entering the Eye Pupil at Different Points

WE have shown[1] that the impression of brightness produced by a light ray which forms an image on a fixed area of the retina depends in high degree on the position of entry of the ray in the eye pupil. For the ratio η of the apparent brightness for peripheral entry to the apparent brightness for central entry, values as low as 0·2 were found for white light and foveal vision. The following new features of the phenomenon have been revealed by later work:

(1) Measurements with white light. When the ray is imaged at the fovea the variation of apparent brightness with point of entry is large whatever the brightness level to which the eye is adapted. When the ray is imaged at a point a few degrees to the side of the fovea (parafoveal vision) there is very little variation of apparent brightness with point of entry for brightness levels below 0·001 c./sq. ft. As the brightness level is increased beyond this value, the effect sets in and is fully developed at a brightness level between 0·1 and 1 c./sq. ft. Fig. 1 shows the variation of $\log_{10}\eta$ with the logarithm of the brightness level, for foveal and parafoveal vision. In these experiments adaptation was secured by viewing a uniform brightness of the desired value. η was deduced from determinations of the smallest intensity of a ray, entering peripherally or centrally and imaged at the fovea or in the parafovea, which the subject could just perceive (liminal brightness increment).

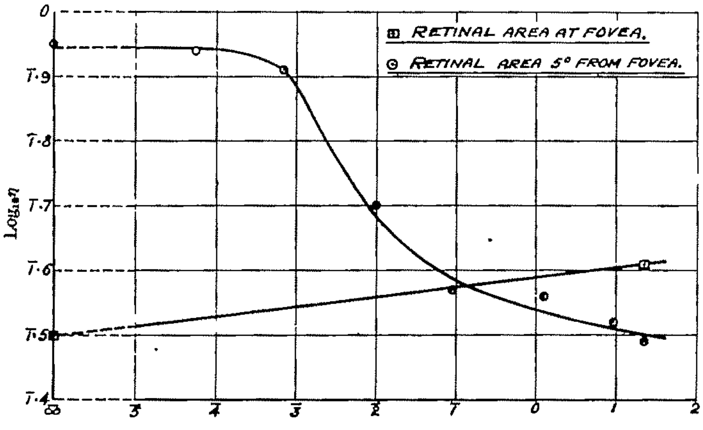

Fig. 1.

(2) Measurements with monochromatic light. Foveal vision. The change of apparent brightness with point of entry shows a relatively small variation with wave-length, being greatest in the blue, least in the yellow. It was observed, however, that the monochromatic light changes colour as its point of entry is varied. The difference ($\delta\lambda$) in apparent hue for central and peripheral entry as a function of wave-length λ for two subjects is depicted in Fig. 2. In addition, in the green and blue-green, the peripheral ray appears more saturated.

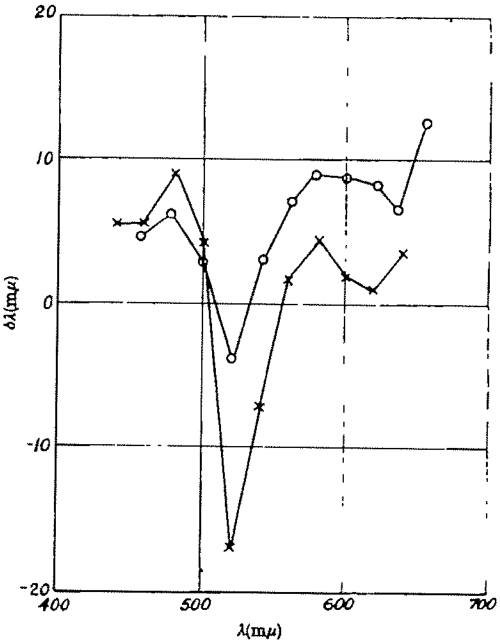

Fig. 2.

Full details of these investigations are being published, but we may perhaps add here the following comments:

(*a*) The retinal origin of the effect is definitely confirmed.

(*b*) For the parafovea, the effect sets in at the brightness level commonly associated with the change-over from scotopic to photopic vision.

(*c*) The three types of receptors of the trichromatic theory must exhibit the effect in different degrees. This appears to be necessary to explain the observed colour change of physically homogeneous light.

Forbidden Transition in the Spectrum of Interstellar Ionized Titanium

AN exploration of the ultra-violet spectra of a number of stars has recently been undertaken in collaboration with Dr. Walter S. Adams, using the aluminized mirror of the 100-inch telescope, a new grating of high efficiency ruled by R. W. Wood on an aluminized Pyrex disc, and an off-axis Schmidt camera[1] of 32 inches focal length which gives, in the second order, a scale of 10·2 A. per mm. Two sharp lines at λλ 3241·99 and 3383·78 the appearance of which suggests an interstellar origin have been photographed in the spectra of five stars of early type: ξ Persei (*Oe*5), λ Orionis (*Oe*5), χ Aurigae (*B*1), χ^2 Orionis (*B*2) and 55 Cygni (*B*2). The interstellar sodium pair ($3s\,^2S - 4p\,^2p^0$) at λλ 3302·38 and 3302·98 were used as standards in determining the wave-lengths of these lines.

Since interstellar lines are likely to arise only from the lowest atomic level, a search was made in all spectra for terms having values close to 30,836·4 and 29,544·3 cm.$^{-1}$, corresponding to the observed wave-lengths. The only terms having even approximately these values are in the spectrum[2] of Ti II: $z^4F^0_{3/2}$ 30,836·52 and $z^4G^0_{5/2}$ = 29,544·37. Absorption from the ground state, $a^4F_{3/2}$, to these levels yields lines measured in the laboratory at λλ 3241·97 and 3383·76.

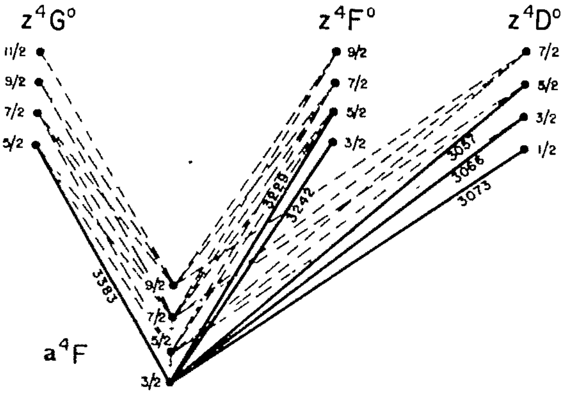

Fig. 1.

Fig. 1 shows that these lines are two of the twenty-eight possible transitions between the lowest term in the spectrum, a^4F, and the strong triad, z^4DFG^0. Four more lines from the ground level, a^4F, should occur at λλ 3229·18, 3072·97, 3036·36 and 3057·43. All these lines may be expected to be weaker than those at λλ 3241·97 and 3383·76. There was evidence for the line at λ 3229·18 ($a^4F_{3/2} - z^4F^0_{5/2}$) on an early plate. A longer exposure shows this line clearly and also the line at λ 3072·97 ($a^4F_{3/2} - z^4D^0_{1/2}$). The detection of these lines at the predicted positions confirms the identification of interstellar titanium. The lines at λλ 3066·36 and 3057·43 are satellites in the $a^4F - z^4D^0$ multiplet and could be detected only with difficulty.

The absence of all strong lines in these multiplets, excepting those arising from the very lowest sub-level, is of considerable theoretical interest. No absorption is observed even from the $a^4F_{5/2}$ level, which has an excitation potential of only 0·012 volt. In spite of the low density of radiation in interstellar space, all four sub-levels of the a^4F term would, at least after a number of years, become occupied in accordance with the Boltzmann relation, and absorption of all lines in each multiplet would necessarily be observed unless spontaneous downward transitions occur between sub-levels of the same term. The absence of absorption from any level but $a^4F_{3/2}$ appears to be definite evidence for the occurrence in interstellar space of the forbidden transitions, $a^4F_{7/2} - a^4F_{5/2}$ and $a^4F_{5/2} - a^4F_{3/2}$, which must emit lines at 76μ and 103μ. The $a^4F_{9/2}$ level cannot be filled unless there is already an accumulation in the $a^4F_{7/2}$ or the $a^4F_{5/2}$ level, and so in all probability no $a^4F_{9/2} - a^4F_{7/2}$ transition (59μ) occurs.

Atoms poised in one of the excited sub-states of the a^4F term in interstellar space can be interrupted and prevented from eventually making a spontaneous descent to the $a^4F_{3/2}$ state only by collisions with other atoms, electrons or with larger particles of matter, by absorption of stellar radiation, or by ionization through cosmic radiation. Collisions with other known atoms of sodium, calcium and titanium and with electrons are not likely to disturb a titanium atom more often than once in several weeks. It is harder to estimate the frequency of collisions with larger particles. Stellar radiation at λ3200 is diluted by a factor of about 10^{14} in interstellar space, according to Eddington's calculations, so that quantum absorptions must occur only at intervals of several centuries. Cosmic radiation may be expected to ionize each titanium atom once in something like 10^6 years, and can safely be neglected. The astrophysical evidence appears, therefore, to be consistent with a mean life-time of any duration up to several weeks for the excited sub-levels in question

It is possible to calculate the probability of the magnetic dipole radiation which is principally involved in the transitions here considered, where the inner quantum number alone changes ($\Delta L = 0$, $\Delta S = 0$, $\Delta J = 1$). Dr. W. V. Houston has very kindly made this computation for me, and finds that the mean life-time of the $a^4F_{5/2}$ state in Ti II is approximately 28 seconds It is, therefore, not remarkable that a titanium atom exposed to the conditions of interstellar space can nearly always return, after any type of excitation, to the lowest sub-level before revealing to us, in absorbing the next quantum of light, what state it occupies.

The theoretical life-time of about 28 seconds for the $a^4F_{5/2}$ state sets an upper limit to the mean density of interstellar matter, in aggregations of any specified size, if we assume a velocity distribution corresponding to Eddington's temperature of 10,000° K., and if we assume that collisions occurring more frequently than once in 28 seconds would maintain a distribution among the atomic sub-levels such that all lines in the multiplets would be observed. Various assumptions as to the sizes of the particles with which the titanium atoms collide lead to limiting densities ranging between 10^{-16} and 10^{-18} gm. cm.$^{-3}$. Since other evidence indicates that the density in space must be far less than this, it is clear that if an atom with a metastable state is to be useful as a density indicator it must have a life-time much longer than that of the $a^4F_{5/2}$ state of Ti II.

A consideration of the spectra and abundance of other elements indicates the possibility of detecting interstellar K I (7664), Ca I (4226), Sr II (4077), Sc II (3580), Fe I (3719) and Al I (3944). There is good evidence for the existence of interstellar K I and Ca I in recent spectra of distant *B* stars An attempt is being made to determine, from the ratio Ca I : Ca II, the electron pressure in interstellar space.

THEODORE DUNHAM, JUN.

Latent Impurities in Electrodes used for Spectrographic Research

IT has often been pointed out that for accurate results in quantitative spectrographic analysis, the standards of known composition, against whose spectra that of the specimen to be analysed is matched, should be made up on a base that simulates as closely as possible the composition of the specimen. This necessity arises from the fact that the intensity of the spectrum shown by a minor constituent of a mixture depends not only on the concentration of the element in question, but also on the nature of the major constituents. It has been shown, for example, that in the case of dilute solutions of lead salts, the lead lines are much stronger if the solution contains a considerable amount of zinc[1].

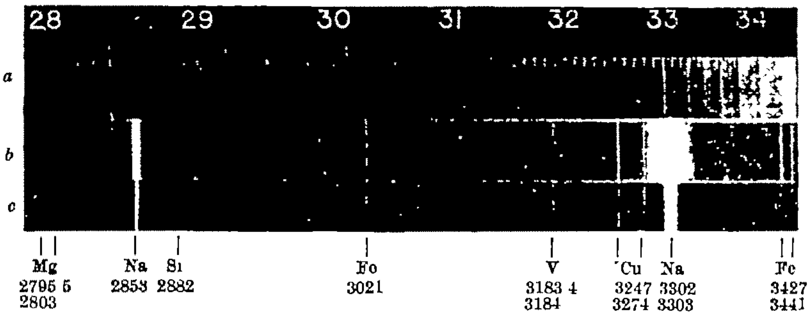

Fig. 1.

In the course of some analyses of animal tissues, which were begun in the Physics Department, Trinity College, Dublin, and are being continued in Cambridge, it has become obvious that this consideration applies not only to the constituents of the specimen, but also to impurities in the electrodes, and that failure to take account of it may render qualitative as well as quantitative results unreliable. The majority of workers in this field, and particularly those who were seeking only qualitative results, and did not, in consequence, have occasion to compare their specimens with standards of known composition, appear to have followed the practice recommended in all the practical handbooks of spectroscopy, of regarding a 'blank' spectrum of the electrodes alone, photographed in juxtaposition to the spectrum of the specimen, as being a sufficient safeguard against interpreting impurities in the electrodes as constituents of the specimen. But the fact is that in the case of carbon or graphite electrodes, impurities the strongest lines of which can only be faintly discerned in the 'blank' spectrum, may leap into prominence as soon as *any* mixture that approximately resembles a tissue ash is introduced into the arc.

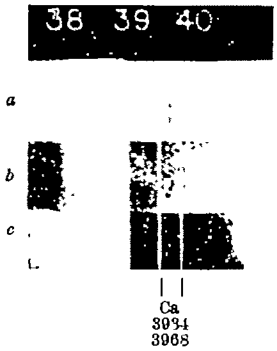

Fig. 2.

The accompanying illustrations (Figs. 1 and 2) show the effect of introducing pure sodium chloride into the arc struck between graphite electrodes, in which the principal impurities are vanadium, calcium and iron. (The manufacturers' claim that the sodium chloride is spectroscopically pure, except for a trace of silver, was verified by examining its spectrum in the silver arc.) It is clear that those lines of vanadium, calcium, iron and copper which are only with some difficulty visible in the spectrum given by the electrodes alone are greatly intensified by the presence of sodium atoms in the arc, while several lines of titanium, which could not be detected at all in the spectrum of the electrodes, also become visible on the plate, though they are not strong enough to show up in the reproduction. The chemical report accompanying the electrodes states that they contain 0·2 parts of titanium per million. The lines of silicon and magnesium, on the other hand, show no sign of intensification.

These results are in harmony with some observations of Papish and O'Leary[2], who found, using graphite electrodes, that the amount of chromium required to produce a spectrum of standard intensity was about sixteen times as great when a dilute solution of chromic acid was put on the electrodes as when an artificial ruby was used. Nobody appears, however, to have drawn from this observation the moral concerning the behaviour of impurities. It is hoped shortly to publish elsewhere, together with the results of the analyses themselves, a list of the elements that are likely, on account of this effect, to give misleading results in biological analyses. Meanwhile, it is clear that reports, by workers who have used carbon or graphite electrodes, on the distribution in living tissues of vanadium, titanium, copper, and possibly other elements, must be treated with reserve.

Luminescence of Solutions of Terbium Salts

VERY dilute aqueous solutions of terbium salts exhibit a bright luminescence when excited by the ultra-violet rays[1]. The maximal excitation is caused by the absorption of the wave-lengths coinciding with the broad absorption band of terbium, stretching from 290 mμ far towards the short wave-lengths[2]. The spectrum of this luminescence consists of 7 bands, each band being nearly 100 A. wide. The wave-lengths and frequencies of the middles of the bands are given in the accompanying table.

The second column gives a rough estimation of the intensities of the bands. It is seen that all the differences between the frequencies of the bands are fairly well expressed by the equation:

$$\Delta\nu_k = K\Delta\nu \qquad (1)$$

where $k = 1, 2 \ldots$ and $\Delta\nu = 272$ cm.$^{-1}$. The maximal divergence is observed for the last difference $- \Delta\nu_6$. The deepest term of Tb^{+++} is a ^7F inverted term[3]; equation (1) should thus hold for the differences between the frequencies of its components also. It may be expected, therefore, that the luminescence bands would be emitted when transitions from a single upper state on all the components of the multiplet of the deepest term take place. This assumption is confirmed by the fairly good agreement which exists between the wave-lengths of one of the luminescence bands (possessing the shortest wave-length) and an absorption band observed in the solutions of terbium salts ($\lambda \sim 488$ mμ). Since the frequencies of the emission bands are considerably smaller than the frequency of the exciting light, it seems that besides the transitions on the deepest term, transitions between excited levels not accompanied by the emission in the visible and ultra-violet regions occur also. It is to be noted that the transitions on the components of the multiplet ^7F presume the breaking of the selection rule[4] for the quantum number j. The length of the afterglow (longer than 0·001 sec.) shows that the level at the transitions on which emission takes place, belongs to the well-screened $4f$ shell; the level at the transition on which absorption takes place belongs probably to the $5d$ shell.

The investigation of the luminescence spectrum of terbium solutions with a spectrograph with a higher dispersion has shown that the bands of the luminescence spectrum have a well-defined structure, depending on the nature of the anion, monovalent and bivalent acids having been investigated.

A similar luminescence is observed with the optical excitation of terbium oxide solutions in concentrated sulphuric acid. A detailed account will be published elsewhere.

Enzymic Properties of Natural Papain

ACCORDING to the generally accepted view, papain is an enzyme which converts proteins (true ovalbumin excepted) into peptones, and is without effect on the latter. Hydrolytic power towards peptones and true ovalbumin is only acquired after treatment with certain reagents ('activators'), especially hydrogen cyanide[1].

We found that freshly tapped latex (milk juice) obtained from fruits of *Carica papaya* at different stages of development and size, grown under natural conditions, splits both gelatin and Witte's peptone and need not be previously activated by hydrogen cyanide. (Ambros and Harteneck[2], investigating latex of fruits grown in a hot-house, sometimes found activity also towards peptones. The differences between their results and ours will be discussed elsewhere.) The degree of hydrolysis of gelatin falls short of that of peptone. On keeping, the activity of the latex towards gelatin is increased and that towards peptone diminished.

The preparations obtained by us from the natural latex by different methods showed different quantitative, and in some cases different qualitative, enzymic properties. Thus, for example, after extraction of the ether-soluble part of the latex, a solid fraction (I) was obtained which showed all the enzymic features of the fresh latex; several such preparations showed 'full activity' towards peptone and almost the same towards gelatin. 'Full activity' connotes that hydrogen cyanide does not enhance the activity of the preparation. Ether-extracted latex yields by centrifuging two fractions: (i) the supernatant fluid showing the hydrolytic properties of the sap; and (ii) the centrifugate, presenting the enzymic features generally attributed to papain, namely, splitting of gelatin, but no action on Witte's peptone; peptone cleavage and enhanced hydrolysis of gelatin after treatment with hydrogen cyanide. On boiling, the supernatant fluid (i) loses its hydrolytic properties, but it can serve as a specific activator of peptone cleavage. On adding boiled supernatant fluid to the centrifugate (ii), the system becomes effective also towards peptone, whilst its activity towards gelatin is diminished.

Contrary to the literature, true ovalbumin is split directly by a latex preparation.

It appears that the activation (or inhibition) by latex bodies of protein cleavage or peptone cleavage respectively are not identical processes. To account for this, it may be assumed (i) that two different enzymes with different specific activators and inhibitors are present in the latex; or (2) that the natural latex constitutes a complex enzymic system resembling the known 'mixed catalysts'. In these catalysts, certain components, which are themselves not necessarily active, induce new qualitative catalysing properties in the system as a whole. The natural latex, on this assumption, constitutes a complete enzyme system, and is therefore able to perform both hydrolytic functions. On partial or total removal of one or the other of these components—by natural accident, instability or storage, or technique of preparation—differences in quantitative effectiveness or even in specificity are produced.

The results presented above show that the accepted definition of the enzymic effectiveness and specificity of the natural papain requires correction. The accepted view is based on experiments which had, out of technical necessity, to be conducted, in the main, with preparations not fully representative of natural conditions.

A detailed report will be given elsewhere.

Attachment of the Sheep Hookworm to the Common Sheep Tapeworm

The study of the manner of feeding of the nematodes inhabiting the alimentary canal of vertebrates is one of the comparatively recent developments of helminthology. Hoeppli, Wetzel and others have shown that many nematodes which possess a well-developed buccal capsule—typified in the Strongylidæ and the Ancylostomidæ—are probably tissue feeders. Thus Wetzel[1] describes the feeding habits of *Chabertia ovina* (Gmelin, 1790) from the large intestine of the sheep and says:

"Longitudinal sections of specimens attached to the mucosa show that the worms have drawn a portion of the stratum glandulare into the subglobular toothless buccal capsule. On its base the tissue is strongly pressed together by the mouth wall and the anterior margin of the buccal capsule, forming a neck-like constriction. Opposite the place to which the parasite is attached a flexure is to be seen in the muscularis mucosa and in the submucosa . . . As to the marked regressive changes of the swallowed tissue and the necrotic masses at the bottom of the buccal capsule we have to assume further a histolytic action of the parasite. . . . From a general physiological point of view the whole process is nothing other than a pre-digestion of the elements of the propria mucosa before they are swallowed by the worm."

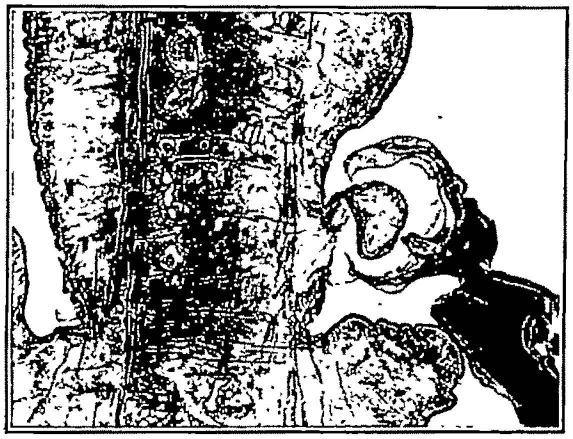

Fig. 1.

On two occasions during the past two years, in the course of frequent examinations of the fresh intestinal contents of sheep for nematodes, I have seen *Bunostomum trigonocephalum*, the sheep hookworm, attached to *Moniezia expansa*, the common sheep tapeworm, though, presumably, it is usual for this hookworm to satisfy its food requirements through the mucous membrane (hæmoglobin may be demonstrated in the worm). In one case, attempted fixation of the parasites to show their relationship was unsuccessful, the *Bunostomum* coming away on immersion in Carnoy, but in the other case the attachment was secure enough to overcome the tendency of the worms to contract on fixation. The accompanying photograph (Fig. 1) illustrates a section through the point of attachment. Although the cestode tissue is badly contracted, seemingly because of the unsuitability of Carnoy as a fixative, it will be seen that the effect of the *Bunostomum* on the cestode tissue is much like the effect of *Chabertia* on the mucous membrane as described by Wetzel. There is a similar withdrawing of a portion of tissue into the buccal capsule, a similar constriction of it at the mouth margin, and a similar tendency, as shown by the transverse muscle fibres, for the deeper lying structures to be drawn down towards the hold of the nematode. Finally, a certain amount of regressive change has taken place in the tissue within the buccal capsule, and the cestode cuticle, the sub-cuticular layer, and the sub-cuticular cells have all been destroyed.

While from this one example, it would be too much to say that *Bunostomum* utilizes *Moniezia* as a source of food, in addition to anything it derives from the mucous membrane, yet the occurrence of this one case has an interesting bearing on the factors which lead the nematodes of the alimentary canal to the mucous membrane. I have so far failed to demonstrate any chemotropic effect the membrane may have on these nematodes, but their possession of a strongly developed stereotropism is readily shown in many ways. They will swim freely in a suitable solution until contact with a membrane surface or its equivalent is attained and then, for some considerable time, they will remain at the surface. Would this stereotropism be sufficient to keep them at the mucous membrane, and is the mere presence of the tissue sufficient stimulus to cause them to feed, or at least, attempt to feed? Or, after all, does the mucous membrane exert a chemotropic effect on the nematodes, and is this particular *Bunostomum* an example of one that has failed to respond?

Structural Laws of the Mammalian Kidney, with a Theoretical Derivation

The structural laws to be described, though independent of theory, may be derived from certain general principles arising out of a 'diffusion-pressure' theory of the kidney. This theory has already been developed to some extent[1]. The principles of derivation are as follows:

(*a*) The renal secretory cells are equivalent in action throughout the Mammalia, and their function is to create a diffusion pressure of urea, etc., in the direction of the lumen.

(*b*) The shape of the kidney and the relations of tubule length to renal length remain uninfluenced by body weight.

(*c*) The mammalian kidney is so constructed that the mean blood and urine concentrations remain independent of the size of the animal.

From the first principle, the following equation may be derived:

$$V(C_U - C_B) = P\, C_B\sqrt{Vknl} \quad . \quad . \quad . \quad (1)$$

Here V is urine rate; C_U, C_B are the urine and blood concentrations; l is the length of the secreting tubule; k is the diffusion coefficient of urea, etc., which may be regarded provisionally as the diffusion coefficient through the tissue; P is a constant. As will be shown later, slight modifications make this equation independent of all changes of blood and urine volume.

Derivation of the structural relations and comparison with the actual data.

From (*c*) and equation (1) we have:

$$V = nl \times \text{a constant} \quad . \quad . \quad . \quad . \quad (2)$$

Since the mean concentration of total nitrogen in the urine is also, from (*c*), independent of body size, and introducing the well-known relation of metabolism to body surface, we derive:

$$nl = W^{0\cdot 666\cdots} \times \text{a constant} \quad . \quad . \quad (3)$$

From (*a*) we have directly that the secreting cells are independent of the size of the animal, or:

$$d = W^{0\cdot 000} \times \text{a constant} \quad . \quad . \quad . \quad (4)$$

The mass of the secreting tissue will be proportional to $nl \times d^2$ and since d is constant, from equation (4), the mass is therefore proportional to nl. Since from (*b*) l will be a linear dimension of this secreting tissue, we get from (3):

$$n = W^{0\cdot 444} \times \text{a constant} \quad . \quad . \quad . \quad (5)$$

and

$$l = W^{0\cdot 222} \times \text{a constant} \quad . \quad . \quad . \quad (6)$$

From the first principle (*a*), and equations (2) and (3), it follows that:

$$ng^2 = V \times \text{a constant} = W^{0\cdot 666} \times \text{a constant} \quad (7)$$

where g is the diameter of the glomerulus.

Hence from (5) we get:

$$g = W^{0\cdot 111} \times \text{a constant.}$$

Collecting the theoretical relations for the single measurements, we have:

$$\begin{aligned} n &= W^{0\cdot 444} \times \text{a constant} \\ l &= W^{0\cdot 222} \times \quad ,, \\ g &= W^{0\cdot 111} \times \quad ,, \\ d &= W^{0\cdot 000} \times \quad ,, \end{aligned}$$

The actual relations established by the minimum square error principle from the logarithmic values of measurements on the mouse, rat, rabbit, cat, echidna, dog, sheep, pig, man, horse and cow, from the available data of Peter, Putter, Inouye, Siewart, Moberg, O'Connor and Conway, etc., are:

$$\begin{aligned} n &= 4580\,W^{0\cdot 456} \\ l &= 1\cdot 78\,W^{0\cdot 196} \\ g &= 55\,W^{0\cdot 109} \\ d &= 50\,W^{0\cdot 006} \end{aligned}$$

where l is length of first convoluted tubule expressed in millimetres and g and d are expressed in microns.

It is hoped to present details shortly in the *Proceedings of the Royal Irish Academy*.

Claims of Geology in School Courses of General Science

THE Interim Report of the Sub-Committee of the Science Masters' Association on "The Teaching of General Science" (reviewed in NATURE of December 19; **138**, 1030) will have been read with much appreciation by all who are interested in school science. While this is under discussion it seems appropriate to direct attention to another report, on "The Teaching of Geology in Schools", by a Committee of Section C of the British Association. This latter report will appear in the forthcoming annual volume of the British Association, but unfortunately it was not available in time for consideration by the Science Masters' Sub-Committee. In it, amongst other recommendations, is a strong plea for the inclusion of a certain amount of geology (with physics, chemistry and biology) in all courses of general science. The Science Masters' Sub-Committee decided not to include any geology (or astronomy) in the syllabuses they suggested, "despite their obvious claims to inclusion". This decision will be regretted, at any rate by geologists, but it may be hoped that it is not final. Indeed the definition of general science arrived at by the Sub-Committee encourages the hope that the claims of geology can scarcely be overlooked: it begins, "General Science is a course of scientific study and investigation which has its roots in the common experience of children and does not exclude any of the fundamental sciences".

It is perhaps not yet generally recognized that many geologists regard the present outlook for their subject with grave disquiet, for although geology has never been taught in schools so widely as other sciences, its position in the educational system has recently become far worse than in the past. It is claimed that there are both cultural and utilitarian grounds for teaching it in schools of all types, but the absence of any mention of it in most curricula is leading to a scarcity of students which threatens to affect seriously the quality of professional geologists and to react adversely on teaching and research in the science.

It may, of course, be held that this position is not the concern of the schoolmaster, but it is noteworthy that the Sub-Committee of the Science Masters' Association takes a wider view of the teacher's responsibilities. While it is suggested that the training of experts cannot form a part of a school course, "the pre-preparation of experts" is one of the schoolmaster's tasks, "and this can best be achieved by broadening the syllabus; for it is at school that particular talents are discovered and their development fostered".

It is hoped that the position of geology in schools, in general science as well as in other courses, may receive sympathetic consideration in the light of the recommendations put forward in the report of the Committee of Section C, for it may be doubted whether one per cent of those who at school receive some training in science have an opportunity to discover any talent for work in geology.

A. E. TRUEMAN.

University of Bristol.
Jan. 18.

The Hexlet

IN Prof. Soddy's recent article[1], the following expression occurs under the root sign in formula (2):

$$6(\alpha\beta + \beta\gamma + \gamma\alpha + \alpha\delta + \beta\delta + \gamma\delta) - 3(\alpha^2 + \beta^2 + \gamma^2 + \delta^2).$$

I find that this expression is equal to $27V^2\alpha^2\beta^2\gamma^2\delta^2$, where V is the volume of the tetrahedron whose vertices are at the centres of the four spheres with bends α, β, γ and δ.

Prof. Soddy, on hearing of this relation, suggested to me that the expression might (following the analogy of the inscribed circle in two dimensions) be related to the bend of the inscribed sphere. This does not turn out to be the case. It is, however, related to the sphere which touches the six edges of the tetrahedron and which cuts the four spheres orthogonally at their six points of contact, and is in fact equal to $12\varepsilon^2$ where ε is the bend of this sphere.

The expression does not change its value if we substitute for any of the original four spheres the opposite members of the hexlet touching the remaining three. The same sphere touches the edges of the four other tetrahedrons which can be formed in this way and thus cuts the spheres orthogonally at twelve other points of contact as well as the original six.

THOROLD GOSSET.

Cambridge.
Jan. 21.

---

[1] NATURE, 139, 77 (Jan. 9, 1937).

THE beautiful result arrived at by Mr. Gosset thus gives an alternative very simple expression for the bend of any of five spheres in mutual contact, namely, $\sigma/2 + \sqrt{3}\varepsilon$, where σ denotes the sum of the bends of the other four, whilst the volume of the tetrahedron involved is $(2\varepsilon)/(3\alpha\beta\gamma\delta)$. It applies in general to tetrahedra for which the *sum* of opposite pairs of edges is, for all three pairs, the same.

I take the opportunity of recording that the tetrahedra formed by joining the four points of contact of any one sphere with the other four, when five are in mutual contact, have the *product* of opposite edges constant. This much simplified the original solution of the problem, and a proof by inversion has recently been sent me by Mr. Hodgkinson. This product is $4\{(\varphi + \alpha)(\varphi + \beta)(\varphi + \gamma)(\varphi + \delta)\}^{1/2}$ and the volume of such tetrahedra is given by

$$V = \frac{2}{\sqrt{3}}\left[\frac{\varphi}{(\varphi + \alpha)(\varphi + \beta)(\varphi + \gamma)(\varphi + \delta)}\right].$$

FREDERICK SODDY.

Oxford.

Points from Foregoing Letters

From observations of disturbances of the earth's magnetism accompanying hydrogen eruptions in the sun, A. G. McNish infers that magnetic disturbance may be attributed to a sheet of current in the electrical layer of the upper atmosphere (ionosphere) together with oppositely directed currents in the earth.

A statistical investigation of the time-distribution of rainfall at Diamond Plantation in British Guiana, over a period of twenty years, leads C. H. B. Williams to the conclusion that there is no support for the local view that more rain is likely to fall at the new or at full moon than during the days just before or just after these phases.

Assuming that the components of a double star are parallel magnetic dipoles giving rise to an electric field, Prof. H. Alfvén calculates that energies of the order of 10^{11} electron volts, such as are found in cosmic rays, could be imparted to electrically charged particles.

Graphs showing the change in apparent brightness according to the point of entry of light rays into the pupil of the eye are given by Dr. W. S. Stiles and B. H. Crawford. The authors have also measured the differences in the apparent hue of monochromatic light in the case of central and peripheral entry.

Photographs of the ultra-violet spectra of several stars indicate, according to Dr. T. Dunham, jun., the presence in interstellar space of ionized titanium with a mean life-time up to several weeks. The author discusses these findings in relation to the temperature and mean density of interstellar matter.

D. A. Webb points out that in spectrographic analyses of tissue ash or similar materials, it is easy to mistake impurities in the electrodes used for the arc for constituents of the specimen, even if a blank spectrum of the electrodes is used as a control. This arises from the fact that the spectrum of the impurities may be enormously intensified by the introduction of the ash into the arc. Copper, vanadium and titanium are the elements most likely to give misleading results from this cause

A table showing the intensity of various bands in the luminescent spectrum excited by the ultraviolet in dilute solutions of terbium salts is submitted by A. Seidel. The author gives a formula for the differences between the frequencies of the seven bands observed and discusses the quantum transition levels which would account for them.

Max Frankel, R. Maimin and B. Shapiro state that the generally accepted view of the hydrolytic properties of papain requires correction. Latex of *Carica papaya* and preparations obtained directly from it, split not only proteins, but also peptones, though papain was supposed to acquire this latter property only by artificial activation. By fractionating the natural latex, several preparations were obtained, among them one which shows all the features generally attributed to papain. Furthermore, a thermostable natural activator inducing peptone cleavage was found. The properties of the various preparations suggest that the natural activation (and inhibition) of protein- and of peptone-cleavage respectively are different processes.

While it is usual for the nematodes of the alimentary canal of vertebrates to attach themselves, firmly or otherwise, to the mucous membrane, D. G. Davey reports an instance in which the sheep hookworm has drawn into its buccal capsule a portion of the common sheep tapeworm. He discusses its bearing on the factors which lead the nematodes to the mucous membrane.

From theoretical considerations, Prof. E. J. Conway has deduced certain relations between the weight of the kidney in mammals and several other factors such as the length of the secreting tubule (l) and the diameter of the glomerulus (g) of the organ in question.

Mr. T. Gosset, continuing the correspondence on the hexlet, states that he has derived a simple expression for the 'bend' of any of five spheres in mutual contact, and Prof. F. Soddy also notes a further development of the subject.

Research Items

Cave Man in Texas, U.S.A.

A JOINT expedition of the University Museum and the Academy of Natural Sciences, Philadelphia, excavated in the Williams Cave, Guadalupe Mountains, Culberson County, Texas, in 1934 and 1935. Dr. E. B. Howard was a member of the expedition in the first year, and in the second Mr. and Mrs. Richard G. L. Ayer, of whom the latter has described the results (*Proc. Acad. Nat. Sci. Philadelphia*, 88, 599). The cave is situated south-west of Signal Peak, the southern termination of the Guadalupe Mountains, two hundred feet up on the side of a steep limestone canyon. Its dimensions are roughly forty feet wide at the entrance and forty-eight feet deep. Three burials were found. The first was in the back half of the northern section eighteen inches below the surface, as was most of the Indian material, and was covered with a large basket, mostly decayed. Two children were found close together, apparently covered with the same netting. The upper skull was covered by a small basket in perfect condition. With this burial were *Olivella* shell and circular pink shell beads. Near were fragments of closely woven cloth and a ball of purple paint. The second was a typical cradle burial, near the north wall. A coarse woven basket was over the burial, and close by fragments of another basket contained painted sotol strips. The cradle was triangular in shape, and the body wrapped in soft hide painted red. This was covered with another piece of hide with the fur on, and over all had been a rabbit fur blanket, now much disintegrated. A bag of charms was on the cradle. The third burial was a bag burial of an adult. The bag was of deer or antelope hide painted red, and contained charred bones. The culture of the archæological remains recovered from the cave corresponds to the Hueco cave dwellers. Twenty-two forms of mammal remains are reported, of which 22·7 per cent are extinct, including the giant sloth. There is evidence of a difference in climate.

Genetics of Cancer

IN the spontaneous development of breast cancer in mice, the genetic factor of the animals and the functional activities of the gonads play important parts. Dr. L. Kreyberg, of Oslo, in the "Reports of the Second International Congress of Scientific and Social Campaign against Cancer" (Brussels, 1936), puts forward the evidence showing that spontaneous breast cancer in mice is in principle equivalent to tumours induced by synthetic carcinogenic agents, the difference being that in the former case the agent is of an intrinsic and physiological origin. The susceptibility to induced tumours and spontaneous breast tumours is genetically different. Work on the genetics of tumour-bearing mice indicates that both chromosomal and extra-chromosomal or cytoplasmic factors are concerned. Dr. Clara Lynch, of the Rockefeller Institute for Medical Research, in a paper in the same volume, shows that the induction of tumours of different types is controlled by different genetic factors, and considers the initial change in carcinogenesis to be of the nature of a somatic mutation. Longevity is important in the development of cancer, and the inheritance of long life as well as susceptibility to mammary cancer and to leukæmia appear to be controlled to a greater extent by the female parent than by the male.

Leeches of the North Sea and Baltic

LIEF. 29, Teil VI.c2 of "Die Tierwelt der Nord- und Ostsee" ("Hirudinea". By Konrad Herter. Akademische Verlagsgesellschaft m.b.H., 1936) contains a very good account of the marine and brackish water leeches of these regions. The marine forms all belong to the Piscicolidæ with the exception of a few visitors, but in brackish waters members of the Glossiphoniidæ, Hirudinidæ and Herpobdellidæ occur. Keys to the sub-orders, families and genera are given and the species belonging to each genus are described and figured. Technique for collecting and preserving follows, with accounts of general anatomy, distribution, movement, nutrition, excretion, respiration, circulation, sense organs, nervous system, reproduction and development. The work is well up to the standard of this most useful series.

Diseases of Garden Plants

THREE fungal parasites of garden plants have been recently described (*Trans. Brit. Mycol. Soc.*, 20, Parts 3 and 4, Nov. 1936). Miss Catherine C. Burt found the fungus *Didymellina dianthi*, a new species, upon the leaves of Sweet William. This name is given to the perfect stage of a fungus the conidial stage of which is known as *Heterosporium echinulatum*. *D. dianthi* is apparently a specific parasite of the Sweet William; carnations and pinks are highly resistant. Mr. N. C. Preston has established the pathogenicity of the fungus *Myrothecium roridum* upon *Viola* plants. It can apparently enter unwounded tissue, and may cause considerable destruction of its host under cultivation. Dr. George Trapp has considered the parasitism of *Botrytis cinerea* on the Japanese laurel, *Aucuba japonica*. The fungus can enter the host through a crack in the cuticle or through a nectary surface, when the atmosphere is completely humid. Symptoms of the disease, and the life-history of the causal organism, are also described.

Lead Arsenate Treatment of 'Leather Jackets'

How best to combat the ravages of the crane fly larvæ, commonly known as 'leather jackets', is one of the problems that besets those interested in turf management. Investigations on the subject are being carried out at the St. Ives Research Station, and some of the more recent experiments have recently been described by R. B. Dawson and R. B. Ferro (*J. Board of Greenkeeping Research*, 4, No. 15). The requirements necessary in the ideal material are several. It must not damage the turf, and preferably not even cause a temporary disfigurement; at the same time it must be economical in use, simple to apply and be harmless to human beings and grazing animals. Lead arsenate satisfies many of these conditions, and experiments carried out with it at a number of different centres have given very promising results. Treatment was successful with either the powder or colloidal form, though preference for the former was shown by many of the workers who had the handling of it, and moreover it is cheaper.

Generally as good control was obtained with the lighter as with the heavier dressings, and since lead arsenate is expensive and the areas requiring treatment frequently large, this is a result of economic importance. It is recommended that before embarking on large-scale dressings, periodical treatment with orthodichlorbenzene emulsion should be carried out to determine whether or not the turf contains the larvæ. The lead arsenate should then be applied in powder form at the rate of 1 oz. per sq. yd. (2·7 cwt. per acre) or if worm control is also desired, at the rate of 1½ oz. per sq. yd. Applications should be made by hand or mechanical distributor after bulking with fine soil or other carrier, at any time during autumn, winter or spring, and grazing animals kept off the turf until the arsenate is well washed into the soil, as it has poisonous properties. The larvæ die in the soil, so no labour other than the distribution of the lead arsenate is involved.

Growth of the Tanna Fault in Japan

During the destructive earthquake of November 26, 1930, in the Idu peninsula, remarkable displacements occurred along the Tanna fault. This fault runs north and south through the western slopes of the volcanoes that lie near the east coast of the peninsula. The intersection of the fault by the Tanna tunnel at a depth of 525 ft. shows that its plane is inclined steeply to the west. In an interesting memoir (*Bull. Earthq. Res. Inst.*, 14, 619–631 ; 1936), Mr. H. Kuno studies the growth of the fault since the Lower Pleistocene age. He shows that the channels of three rivers on the west side of the fault now lie 1 km. to the south of their former continuations on the east side and that the slope of the ground on the west side, if produced, would lie about 100 m. above the slope on the east. Cutting the map along the line of the fault and shifting the west side through a distance representing 1 km. to the north, and lowering the height of each contour-line on that side by 100 m., the two sides fit well together, except in the northern part of the district, in which the vertical displacement was much less. Mr. Kuno thus concludes that the block on the west side of the fault was shifted about 1 km. to the south over the greater part of the fault and raised 100 m. or more in its southern part, relatively to the block on the east side. It is interesting to notice that the displacement during the Idu earthquake of 1930 was similar, the greatest relative movements of the western block being 1·2 m. to the south and 0·6 m. upward.

Optical Experiments with Pinholes

Mr. F. J. Hargreaves has recently published a paper under the above title in which he describes how the diffraction phenomena produced by telescopes can be reproduced by looking through pinholes of different diameters (*J. Brit. Astro. Assoc.*, 47, 2; December 1936). It is quite easy to see the phenomena of a single star, double stars or even of planets, the latter being simply illustrated by the warp and weft of a piece of fabric remaining invisible through a small pinhole, though easily seen through a large one. The large diffraction pattern in the former case hides the details, and in the same way fine detail on a planet or the moon is invisible in a telescope of small aperture, though easily seen in one of large aperture. The experiments are very clearly described, and users of telescopes will find much that is both interesting and instructive in the paper.

Time Effects in Spectrophotometry

Mr. W. M. H. Greaves has a paper under this title in *Mon. Not. Roy. Astro. Soc.*, Supplementary Number, 96, 9 (October 1936). He points out that Schwarzschild's law, $D = \varphi(It^p)$, where D is the optical density of the image or any other measure of photographic effect, I is the intensity of the light, t the time of exposure, and p the constant for any particular plate, is only a first approximation. The work of Kron and others has shown that it is valid only over a very limited range, and errors occur in spectrophotometric measurements which involve the use of different exposure times, if the law be applied. Mr. Greaves is concerned with applications to practical spectrophotometric technique, and develops simple formulæ which are capable of high accuracy over the limited ranges of the variables employed in practice. Two formulæ are given which correct for time effects, and it is suggested that they may be of assistance to workers who desire to be free from the restriction of using identical exposure times in all comparisons—a procedure which seriously limits the output. When unequal times are used, it is essential that the character of the emulsion should be investigated, and also that the value of a certain constant ε should be determined. No account has been taken of temperature effects in the paper, but from the work of Webb (*J. Opt. Soc. Amer.*, 25, 4; 1935) it does not appear that serious errors will be introduced, for ordinary working temperatures, if the variation of ε with temperature be ignored. It is important, however, to calibrate plates at approximately the same temperature as that at which they are to be exposed.

Controlled Grain Size in Steel

It has been known for some time that by a control of the degree of de-oxidation of molten steel prior to casting, combined with the addition of a small amount of aluminium, steels can be produced with a grain size which is much finer than is normally the case. The majority of the work hitherto published is of American or German origin, and a paper read by T. Swinden and G. R. Bolsover before the Iron and Steel Institute in September last represents the first publication in Great Britain on an exceedingly important subject. The authors show that the fine-grained steel so produced is characterized by a very much higher impact value than is the normal material. In the case of nickel-chrome steels subject to 'temper brittleness', it is shown that these fine-grained steels, although still showing this phenomenon, are less affected than are the steels as ordinarily manufactured. The low-temperature brittleness produced by tempering in the region of 250°–400° C. after a preliminary quenching is less pronounced in the fine-grained steels than in the coarser ones. An exceedingly interesting field is opened up by the proof that these fine-grained steels retain their impact value to a very much greater extent when strained and re-heated to 250° C. than do materials of similar composition but with larger crystal size. The ageing after quenching at 650° C. again does not produce anything like the degree of embrittlement in the new material as obtains with ordinary steels. Cracking during hardening appears to be eliminated or greatly reduced, while the machinability of the 'controlled grain' steel is not appreciably different from that of ordinary engineering materials of similar composition.

Physics of the Solid State

FIFTIETH ANNIVERSARY OF THE PHYSICAL SOCIETY OF ZURICH

THE Physical Society of Zurich celebrated its fiftieth anniversary by holding a meeting on January 13–16 to discuss the "Solid State".

This Society was originally founded by students in order to discuss physical and technical problems. One of the early and rather unusual rules governing the selection of new members was that no professors should be admitted. This rule was abandoned later when the Society included in its list of members such distinguished names as: P. Weiss, A. Einstein, M. von Laue, P. Debye and E. Schrodinger, who were all at some time on the staff of either the University or the Technical High School in Zurich.

The jubilee meeting was opened by the president of the Swiss Board of Education, and his address was followed by a speech from Prof. P. Weiss, of the University of Strasburg, who represented the foreign members of the Society.

The first scientific address was given by Prof. P. Niggli, of the Technical High School, on the subject of "Mineralogical Problems of Crystal Structure". Prof. Niggli gave first a general survey of the various crystal types and discussed in particular the case in which whole groups of the constituent parts of the crystal are partially substituted by other groups without thereby altering the lattice. He gave the rules governing these substitutions, and discussed the problem on the basis of the geometrical structure theory.

On the following day, Prof. W. L. Bragg, of the University of Manchester, gave an account of the structure of binary alloys in connexion with the Hume-Rothery rule, and discussed the lattice transformation in alloys in their relation to order-disorder phenomena.

Prof. P. Debye, of the Kaiser Wilhelm Institute of Physics, Berlin, dealt in his lecture with the semi-crystalline nature of liquids. He discussed the effect of the waves of thermal agitation in a liquid upon the scattering of monochromatic light by the liquid. Whereas, in a gas, light originally monochromatic becomes slightly less so after it is scattered, in an ideal crystal, this light splits into two components; and in a liquid, generally speaking, into three spectral lines, except when the coefficient of expansion becomes zero, as for example in water of maximum density, where only two lines appear, as predicted by the theory. From these experiments, Prof. Debye concludes that a liquid is, on the whole, much nearer to a solid than it is to a gas.

On the following day, Dr. A. Müller, of the Royal Institution, London, gave a summary of the work on long-chain compounds of the paraffin type. He discussed the relations between the structure and physical properties of these substances and dealt with the problem of crystal transformations.

Prof. H. Mark, of the University of Vienna, lectured on the kinetics of polymerization of certain substances which form very long chains, and gave an account of the elasticity of rubber, which he treated as a problem of statistics of the configuration of these long chains.

The evening lecture was delivered by Prof. A. Sommerfeld, of the University of Munich, who gave an excellent account of the modern theory of the metallic state, and of the specific heat and electrical conductivity of metals.

The final address was by Prof. M. von Laue, of the University of Berlin, who discussed the theory of the "Kossel- and Kikuchi-lines" which are observed when a source of X-rays or electron waves is placed inside a crystalline medium.

The papers presented at the meeting will be published together.

The meeting was well organized and attended, for which the president of the Society, Dr. R. Sanger, was largely responsible. At the same time, there was an informal atmosphere and lively discussion. The meetings arranged by the Physical Society in Zurich nearly every year are now well-known in scientific circles, and provide opportunities for the exposition of recent scientific work in a place convenient for scientific men of all nations. A. M.

International Cancer Research

REFERENCE has already been made in these columns to the Second International Congress of the Scientific and Social Campaign against Cancer which was held in Brussels last autumn (NATURE (1936), 138, 727). The text of fifty-five reports or reviews which were read at the Congress have now been published*. Each report is given at length in one of the six official languages, while summaries of the reports are given in all six languages. Some of the reports, such as that of Cook, Haslewood, Hewett, Hieger, Kennaway and Mayneord on "Chemical Compounds as Carcinogenic Agents" and that of Reding on "Predisposition and Resistance to Cancer", have good bibliographies, while others have no references. The greater part of the volume is concerned with the biology, diagnosis and therapy of cancer, and there are interesting reviews on the statistical investigation of mortality from cancer in different States and among different races.

The last four papers on the statistics of morbidity and mortality from cancer are from London, Munich, New York and Batavia, and show that the total mortality from cancer is of the same order in almost all parts of the world. As Dr. Cramer points out, "cancer in man is an experiment carried out on man of which the end results are represented by the cancer mortality statistics, while the beginning of the experiment is unknown". The problem of the cause of cancer is to determine the beginning of the experiment, and hints of this are given by analysis of the statistics. Dr. Bonne gives relative cancer mortality figures for Malays and Chinese in Batavia, Chinese in Singapore, Filipinos in Manila, Japanese in Tokyo and Austrians in Innsbruck. The total mortality from cancer in these groups is of the same order, but the distribution according to sites is quite different. Cancer of the liver, which is rare in Europe, is common in the East, and cancer of the lung is more common in Europe than in the East. The results given in these statistical papers show the magnitude and extent of the fight against cancer.

---

* IInd International Congress of the Scientific and Social Campaign against Cancer. Vol. 1. Reports. Pp. xvi+503. (Bruxelles: Ligue Nationale Belge contre le Cancer, 1936.)

The fact that these reviews are given by invitation by scientific workers of sixteen different countries indicates how widespread is the effort to combat malignant disease. The report brings together work from research workers in chemistry, histology, medicine, surgery, radiology, geography, and statistics, and will no doubt have a beneficial influence in making workers aware of what is being done in cancer research outside their own fields. It is probably as good a general review of the whole field as can be found, although there are too few illustrations in some parts of the work, and several chemical formulæ are incorrectly represented.

The reports deal mainly with work of the last three years, and if similar publications are produced at each triennial congress, they would continue to improve co-operation between research workers in different countries and sciences.

Historic Flora of Mexico

THE Smithsonian Institution has just received, for study and identification of specimens, part of the celebrated Sesse and Mocino collection of the flora of Mexico, which recently came to light in Madrid after more than a century. The collection was sent by Spanish officials just before the outbreak of the revolution to Dr. Paul Standley, of the Field Museum of Natural History in Chicago, an authority on the plants of Mexico. Dr. Standley has distributed it to American institutions specializing in various plant families represented, for study under his direction.

The story of this collection is one of the most colourful in the history of botanical exploration. In 1787, Charles III of Spain sent to Mexico a botanical expedition headed by Dr. Martin Sesse y Lacasta, the most eminent of Spanish botanists, for the purpose of making a complete collection of the flora of Mexico and setting up a chair of botany in the National University at Mexico City. The lectures of Sesse and his companions aroused the interest of a young Mexican physician, Dr. José Mariano Mocino. He became so absorbed in botany that he gave up his practice, obtained an appointment as a member of the expedition, and for more than twenty years engaged in almost constant exploration. He covered all central Mexico, and made trips so far south as Guatemala and so far north as California. In 1804, Sesse and Mocino went to Spain, where they began to work up their collections. Sesse died five years later, and Mocino was made director of the Cabinet of Natural History in Madrid. About this time, Madrid was invaded by the French. A change in Government meant nothing to the Mexican botanist, absorbed in the plants for which he had risked his life so often. He was popular with the invaders, and they did not disturb him. Then the French were driven out and the vengeance of the Spaniards, incensed at his "traffic with the enemy", fell upon the head of Mocino. He was thrown into prison and placed in chains, to be rescued by the return of the French army.

Once again the French were driven out. This time Mocino took no chances. He loaded his manuscripts and drawings into a mule cart and, old and feeble as he was, walked beside it throughout the hasty retreat across the mountains. He finally arrived safely at Montpellier in France, but nearly blind and penniless. He might have starved had it not been for the friendship of the celebrated Swiss botanist De Candolle. The latter, however, borrowed his drawings and took them with him to Geneva. Mocino in the meantime was negotiating to return to Spain, and finally was assured that he would not be bothered. He wrote to De Candolle asking for the immediate return of his drawings. The result was one of the most extraordinary incidents in the history of botany. De Candolle asked for volunteers—anybody in Geneva with any artistic talent—to copy them as a patriotic duty. The volunteers came—society girls, college students, ministers. Altogether 120 of them were put to work and completed the job in ten days. With his drawings returned, Mocino started back to Spain. In Barcelona he was taken ill and died, giving his drawings to a physician who had befriended him. This man apparently attached no value to them and they disappeared. Had it not been for De Candolle's copies, they would have been lost completely to science.

Meanwhile, the manuscripts of Sesse and Mocino and the plants they had collected remained at Madrid. Nobody attached any value to them or paid any attention to them. It was not until 1888, nearly a century after the collections were made, that the manuscript was published in Mexico City. Meanwhile most of the plants had been rediscovered and described, so that Mocino and Sesse were deprived of their hard-earned glory.

The specimens, however, remained at Madrid. Many of the species described in the manuscript could not be identified with any known in Mexico at the time of the publication, and it was impossible to match the descriptions and other specimens. Perhaps there are species still unknown to science. It is noteworthy that Mocino was especially interested in medicinal plants, and spared no effort to obtain everything to which curative properties were ascribed by natives.

The Pontifical Academy of Science

FEDERICO CESÍ of the Princes of Acquasparta, John Heck, a Dutchman, Francesco Stelluti of Fabriano and Anastasio de Filiis, Count-Palatino of Terni, founded at Rome on August 17, 1603, an Academy of Science and called it the *Lynceorum philosophorum Ordo seu Consessus seu Academia* with the motto: *Sagacius ista.* Galileo Galilei joined it after 1610.

Finis eius, they proclaimed, *est rerum cognitionem et sapientiam non solum acquirere, recte pieque simul vivendo, sed et hominibus voce et scriptis ubique ullius noxa pacifice pandere.*

Though its fortunes varied, the Academy's aims and activities were always scientific.

In 1847, Pope Pius IX, continuing the interest that previous popes had shown, decided to restore the Academy with a new constitution; he reconfirmed its possession of the Senatorial Palace on the Campidoglio, began the regular publication of the "Acts", and placed it in direct dependence upon the pope and his government with the new title of the "Pontifical Academy of the New Lincei". Later, in 1877, it was still further enlarged by Leo XIII, who increased the number of its fellows (*Soci*) and began the publication of the "Memorials".

Finally, in 1922, His Holiness Pius XI changed its residence, which after 1870 had been the Palace of the Apostolic Chancellery, to the Vatican Gardens, giving it the beautiful little house of Pius IV which is one of Ligorio's finest works of art, and providing generously for its financial rehabilitation. In 1923, he altered its name to "Pontifical Academy of Science—the New Lincei".

Following the Papal Letter, "*In multis solaciis*" of October 28, 1936, and in view of the great importance attaching to the Academy itself, he decided to adapt it to the new and more obvious needs of the times by providing it with a new constitution and a complete revision of its membership, keeping, however, for its former members their rank of 'fellows'.

This new Academy, "The Pontifical Academy of Science", is directly dependent upon the Pope himself, and is composed of seventy 'Pontifical academicians', appointed by the Pope, belonging to every nation and religion, chosen from among the most famous men of science in the world. To these are added the 'Supernumerary academicians' by reason of their office, and the 'Honorary academicians' by reason of their good services towards the Academy itself. *Ab eis itaque Apostolica haec Sedes id auxilii ac decoris expectat ac praestolatur, cuius hic veluti doctorum hominum Senatus, seu "Scientificus" Senatus, certum portendit auspicium.*

The members of the Academy aro as follow:

Presidente, Prof. P. Agostino Gemelli, O.F.M.; *Segretario*, Comm. Prof. Giuseppe Armellini; *Tesoriere*, M. se Gr. Uff. Prof. Lepri Giuseppe; *Bibliotecario*, P. Don Anselmo Albareda, O.S.B.; *Censori*, S. E. Gr. Uff. Prof. Emilio Bianchi, S. E. Gr. Uff. Prof. Filippo Bottazzi, *Cancelliere dell' Accademia*, Comm. Dott. Pietro Salviucci.

Accademici Pontifici Onorari. Emo Card. Gaetano Bisleti, Emo Card. Eugenio Pacelli, Emo Card. Francesco Marchetti Selvaggiani, P. pe Ludovico Chigi Albani della Rovere, Prof. Pietro De Sanctis.

Accademici Pontifici. Abderhalden, Emil (Halle), Amaldi, Ugo (Roma), Armellini, Giuseppe (Roma), Barrois, Charles (Lille), Bianchi, Emilio (Milano), Birkhoff, George David (Cambridge, Mass.), Bjerknes, Vilhelm Frimann Koren (Oslo), Bohr, Niels (Kopenagen), Boldrini, Marcello (Milano), Bottazzi, Filippo (Napoli), Branly, Edouard (Paris), Buytendijk, F. J. J. (Groningen), Carathéodory, Constantin (Munchen), Carrel, Alexis (New York), Castellani, Aldo (Roma), Colonnetti, Gustavo (Torino), Crocco, Gaetano Arturo (Roma), Cuenot, Lucien (Nancy), Dal Piaz, Giorgio (Padova), Debye, Peter (Berlin-Dahlem), De Filippi, Filippo (Roma), de la Vallée Poussin, Charles (Louvain), Fauvel, Pierre (Angers), Gemelli, Agostino (Milano), Gherzi, Ernesto (Zi-ka-wei, Shanghai), Ghigi, Alessandro (Bologna), Gilson, Gustave (Louvain), Giordani, Francesco (Napoli), Giorgi, Giovanni (Roma), Godlewski, Emil (Krakow), Gola, Giuseppe (Padova), Grégoire, Victor (Louvain), Giudi, Camillo (Torino), Guthnick, Paul (Berlin-Neubabelsborg), Houssay, Bernardo (Buenos Aires), Keesom, Wilhelmus Hendrikus (Leiden), Lemaître, Georges (Louvain), Lepri, Giuseppe (Roma), Levi-Civita, Tullio (Roma), Lombardi, Luigi (Roma), Luigioni, Paolo (Roma), Marconi, Guglielmo (Roma), Mendes Correa, Antonio Augusto (Porto), Michotte, van den Berch Albert (Louvain), Millikan, Robert Andrews (Pasadena, Calif.), Morgan, Thomas Hunt (Pasadena, Calif.), Nobile, Umberto (Napoli), Noyons, Adriaan Karel Marie (Utrecht), Panetti, Modesto (Torino), Parravano, Nicola (Roma), Pensa, Antonio (Pavia), Petritsch, Ernst Felix (Wien), Picard, Emile (Paris), Pistolesi, Enrico (Pisa), Planck, Max (Berlin), Rasetti, Franco (Roma), Rondoni, Pietro (Milano), Lord Rutherford of Nelson (Cambridge), Schrödinger, Erwin (Graz), Sherrington, Sir Charles (Oxford), Silvestri, Filippo (Portici), Sperti, George (Cincinnati, Ohio), Taylor, Hugh Stott (Princeton, N.J.), Toniolo, Renato (Bologna), Tschermak-Seysenegg, Armin (Prag), Vallauri, Giancarlo (Torino), Vercelli, Francesco (Trieste), Volterra, Vito (Roma), Whittaker, Edmund Taylor (Edinburgh), Zeeman, Pieter (Amsterdam).

Accademici Pontifici Soprannumerari. Albareda, Anselmo, prefetto della Biblioteca Apostolica Vaticana; Gatterer, Aloys, prefetto del Laboratorio Astrofisico della Specola Vaticana; Mercati, Angelo, prefetto dell' Archivio Segreto Vaticano; Schmidt, Wilhelm, direttore scientifico del Museo Missionario etnologico lateranense; Stein, Johann, direttore della Specola Vaticana.

University Events

CAMBRIDGE.—Prof. W. J. de Haas, of Leyden, has been appointed Scott lecturer for the year 1937–38.

Prof. L. T. Hogben will lecture in the Zoological Lecture Room on Wednesday, February 10, at 5 p.m., on "Some Neglected Aspects of the Species Problem".

OXFORD.—The following appointments to professorships have been made: Mr. C. N. Hinshelwood, Trinity College, to the Dr. Lee's chair of chemistry; Mr. Hugh Cairns, Balliol College, to the Nuffield chair of surgery; Mr. R. R. Macintosh, to the Nuffield chair of anæsthetics.

Science News a Century Ago

The Ashmolean Society

In Oxford, on February 6, 1837, at a meeting of the Ashmolean Society, "Mr. Holme of C.C.C. read a paper on the formation and habits of the British aquatic coleoptera, which are included in the sections *Hydradephaga* and *Phithydrida* of Macleay, and exhibited specimens which showed the voracity of some specimens of the genus Dyticus, and concluded by drawing attention of the members to the question whether the mole cricket is able to swim, which Mr. Curtis thinks probable, from the resistance which the thorax and elytra offer to water. Mr. Duncan read a paper, in which he gave an outline of the progressive development of animals from their embryo to their perfect state especially of the frog—of one species of which, the *Rana paradoxa*, he exhibited a specimen in the tadpole state, nearly transformed." (*Athenæum*.)

Of the individuals mentioned in this note, one was presumably Alexander Macleay (1767–1848), F.R.S., the entomologist and colonial statesman, another Philip Bury Duncan (1772–1863), keeper of the Ashmolean Museum in 1826–55, and a third John Curtis (1791–1862), the author of "British Entomology" (1824–39).

Lieut. Wellsted's Exploration of Arabia

At a meeting of the Linnean Society held on February 7, 1837, the chairman, A. B. Lambert, spoke of the researches of Lieut. Wellsted in Arabia Felix, and said that this traveller had added much to the knowledge of the natural history of the district. He had ascertained the tree producing myrrh, and also the dragon-tree. He had surveyed the northern coast of the Red Sea, where he had many opportunities of confirming the descriptions of Bruce, whom he considered the most accurate traveller in those regions who had ever returned to Europe. Mr. Lambert also exhibited some specimens of manna brought by Lieut. Wellsted from Mount Sinai, considered to be the produce of a tamarisk, which was supposed to be identical with that on which the children of Israel fed in the wilderness.

Aylmer Bourke Lambert (1761–1842), well known for his botanical writings, was an original member of the Linnean Society, while James Raymond Wellsted (1805–42) was an officer in the service of the East India Company.

The Properties of Electricity

On February 7, 1837, F. W. Mullins, M.P., sent a communication to the *Philosophical Magazine* (**10**, 281) entitled "On the Development and Action of Electricity in Voltaic Combinations". In his concluding paragraph he said: "I believe light, as well as heat, to be a property of electricity, else, how account for its existence in its *purest form in vacuo*, where electricity is the only agent? But I shall refer to these subjects again and at greater length when I have more leizure than I have at present, merely adding that I do not believe my views to be irreconcilable with Mossotti's theory, and that I am quite satisfied that though chemical action may be supposed to develop electricity, still electricity is the prime mover; electrical and material attractions and repulsions, when brought into play by certain arrangements of elements, inducing and creating all chemical phenomena. . . ."

Heat Transfer in Locomotive Boilers

At a time when the caloric theory of heat still held sway, Jacob Perkins, on February 7, 1837, read a paper to the Institution of Civil Engineers entitled "On Locomotive Engines and the means of Supplying them with Steam". The practical defects of the existing system of locomotives arising from the furring up or burning out of the tubes of the boiler, he considered, could be overcome through the medium of steam surcharged with caloric. If a tube hermetically sealed be filled to a sixtieth of its contents with water, the steam arising from the water will not acquire sufficient elastic force to burst the tube; but will have a remarkable property of transferring heat. The steam in the vertical tube being saturated with heat, becomes a medium through which the heat ascends by its own levity, so that the tube would become red hot were it not immersed in water.

Perkins, who was born in America in 1766 and died in London in 1849, was a pioneer in the use of high-pressure steam, and had before 1837 constructed boilers and engines working at pressures of 800–1,600 lb. per sq. in.

Science News in the *Athenæum*

In its issue of February 11, 1837, the *Athenæum* gave the following notes of scientific interest.

French Academy of Sciences. M. Becquerel is elected vice-president of the French Academy of Sciences for 1837, by a large majority of votes; and M. Magendie, the last vice-president, passes on to the presidency. The Minister of the Interior has commanded a bust of the late celebrated botanist, M. de Jussieu, to be executed for the Academy, by the skilful hands of M. David.

Acoustics. MM. Cagniard Latour and Demonferrand have invented an instrument which they propose naming the Acoustic Pyrometer, and which will emit sounds according to the temperature in which it may be placed.

M. Melloni. The able and celebrated philosopher, M. Melloni, who was exiled from Italy, has been recalled by the Duchess of Parma: M. Arago appealed to Prince Metternich on his behalf, at the same time laying before His Highness an analysis of his merits, and his beautiful discoveries. The Prince submitted this statement to the Duchess and interceded, and consequently M. Melloni is now at liberty to return to his native country.

Societies and Academies

London

Royal Society, January 28.

R. D. Preston and W. T. Astbury: The structure of the wall of *Valonia ventricosa*. The cell wall of *Valonia ventricosa* has been studied in detail by means of X-ray diffraction photographs and the polarizing microscope. It consists of layers in which the cellulose chains in any one layer are inclined to those in the preceding and subsequent layers at an angle which is on the average rather less than a right angle. The chains of one set of layers form a system of meridians to the wall, while those of the other set build a system of spirals closing down on the two 'poles' defined by the meridians. The development of the rhizoids is associated with regions of the wall adjacent to the poles of the spiral. The plane of spacing, 6·1 A., of the cellulose crystallites is, roughly speaking, confined within an angle of about 60° to the wall surface. The path of the cellulose spiral is that of a logarithmic (equiangular) spiral described on the surface of a sphere or prolate spheroid.

W. D. WRIGHT: The foveal light adaptation process. A further series of observations on adaptation phenomena have been recorded by the binocular matching method, in which effects induced by light-adapting the right eye are measured relative to the constantly dark-adapted left eye. For white adaptations, the sensitivity of the red and green responses is inversely proportional to the adaptation intensity, and the recovery curves for these responses are linear; for the blue, the response is reduced to a less extent than for the red and green, and the recovery curves are non-linear. They may indicate a monomolecular or bimolecular reaction, whereas the red and green processes appear to recover at a constant rate. With red adaptations, the green recovery is linear and the red non-linear, but while the red sensitivity is inversely proportional to the adaptation intensity, the green is reduced to a relatively less extent as the adaptation is increased. With green adaptations, the reverse occurs. The application of the method of observation for clinical purposes is suggested and the relation of the results to illuminating engineering problems emphasized; in particular, an 'adaptation factor' should be measured in heterochromatic photometry, if the true visual efficiency of light sources is to be found.

W. S. STILES and B. H. CRAWFORD: The effect of glaring light source on extrafoveal vision. The smallest difference of brightness between a test object and its background such that the presence of the object can just be detected (the liminal brightness increment) is in general raised if there is an unshielded light source in the field of view. If the light source produces an illumination E ft. c. at the eye and is located at a point $\theta°$ from the test object, then for foveal vision of the test object the increase in the liminal brightness has been found to be equal to that which would be produced in the absence of the light source by raising the background brightness from its original value B to the value β, where $\beta = B + kE/\theta^n$ and k and n are constants having values approximating to 10 and 2 respectively. Tests were made to see if a similar formula applies when the test object is viewed by extrafoveal vision. Four extrafoveal points situated at approximately 5°, 10°, 25°, and 50° from the fovea in the temporal, lower, upper, and nasal meridians respectively, were studied for two subjects. The formula was found to be true, in general, as an approximation, and for k and n the values 16 and 2 respectively were derived as representative for extrafoveal vision.

Royal Irish Academy, December 14.

J. J. NOLAN and P. J. NOLAN: Atmospheric electric conductivity and the current from air to earth. Measurements were made at Glencree of the field and air-earth current by C. T. R. Wilson's method. Hence the conductivity at the earth's surface was determined. Simultaneous observations of the concentrations of positive and negative ions were made. The mean mobilities of the ions were determined. Values of the total conductivity calculated from the results found exceeded by only about ten per cent the values derived from the Wilson experiment.

Edinburgh

Royal Society, January 11.

F. FRASER DARLING: Observations on animal sociality. Animal sociality is difficult to define because of widely differing foundations and the existence of different types within one species. Red deer show closely-knit female groups, loose stag companies and, at the breeding season, harem formations superimposed on the hind groups. The matriarchal system emerging is an evolutionary advance on small patriarchies in grazing herds. Flocking of birds is found outside or within the breeding season. Flocks on a traditional family basis are rare. Observations on herring gull colonies showed that egg-laying was earlier and time taken less in the larger colonies. This was reflected ecologically in the higher survival rates in larger groups.

H. S. RUSE: The geometry of Dirac's equations and their expression in tensor form. Associated with Dirac's equations for general relativity, as obtained from the theory of two-component spinors, are four null vectors which may be regarded as defining the vertices of a skew quadrilateral upon a quadric surface in a three-dimensional projective space. A study of this simple geometrical configuration throws light upon the relationships of the various tensors associated with the Dirac theory, the whole of which can be thrown into a tensor form not explicitly involving spinors.

Moscow

Academy of Sciences (*C.R.*, 4, No. 2; 1936).

J. DUBNOV and N. EFIMOV: Pairs and bundles of grids.

M. M. GUREVIČ: Change in the brilliancy of a bundle of rays on refraction.

N. IVANOVA: Route of the particles comprising the showers of ultra-penetrating rays.

W. A. OSIPOV-KING: A new mode of construction of polarization prisms.

L. M. SCHAMOVSKIJ: The elementary photographic process in ion crystals.

F. M. ŠEMJAKIN: The question of periodic reactions.

A. POLESICKIJ: The lower limit of the formation of mixed crystals of a new type.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, February 8

University of Leeds, at 5.15.—Dr. J. Hammond, F.R.S.: "Growth and the Function of the Mammary Gland".*

Tuesday, February 9

St. Mary's Hospital Medical School, at 5.30.—Prof. E. D. Telford: "Some Disorders of the Peripheral Circulation" (succeeding lectures on February 16 and 23).*

Wednesday, February 10

Bedford College for Women, at 5.15.—Dr. Friedrich Zeuner: "The Climate of the Countries adjoining the Ice-Sheet of the Pleistocene".*

Royal Society of Arts, at 8.15.—Olaf Bloch: "Applications of Photography to Scientific and Technical Problems".

Thursday, February 11

Institution of Civil Engineers, at 6.—H. Coyne: "The Construction of Large Modern Water Dams" (Joint Meeting with the British Section of the Société des Ingénieurs Civil de France and the Institution of Structural Engineers).

Royal Aeronautical Society, at 6.30—(at the Royal Society of Arts, 18 John Street, Adelphi, W.C.2).—F. W. Meredith and P. A. Cooke: "Aeroplane Stability and the Automatic Pilot".

Friday, February 12

Royal Astronomical Society, at 5.—Annual General Meeting.

J. H. Reynolds,: Address on the award of the Gold Medal to Dr. Harold Jeffreys.

Royal Institution, at 9.—Prof. I. M. Heilbron, F.R.S. "Pigments Associated with the Fatty Tissues of Plants and Animals".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Engineering Inspector in the Roads Department of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (February 11).

Head of Engineering Department in the North Staffordshire Technical College—The Clerk to the Governors, Town Hall, Hanley, Stoke-on-Trent (February 17)

Lecturer in Physics and Mathematics in the Croydon Polytechnic—The Education Officer, Education Office, Katharine Street, Croydon (February 27).

Director of Antiquities, Palestine—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1 (March 31).

Analyst and Demonstrator at the Harper Adams Agricultural College, Newport, Shropshire—The Principal.

Chief Chemist of the Indian Jute Mills Association, Calcutta—S. G. Barker, 191 Coombe Lane, Wimbledon, S.W.20.

Peking Man: The New Skulls and the Evolutionary Problem

ALL but ten years have elapsed since the investigations initiated through the palæontological researches of Dr. J. G. Andersson of the Chinese Geological Survey culminated in the identification of Peking man. It was in 1927 that the late Dr. Davidson Black boldly, on the evidence of a tooth, differentiated a new genus of man, *Sinanthropus pekinensis*. His temerity was fully justified two years later when in December 1929, Mr. W. C. Pei found the first skull of Peking man in the cave of Choukoutien ; but it is only now, after the discovery of the three new skulls in November last, which are described by Prof. Franz Weidenreich in this issue of NATURE (see p. 269), that it is possible to appreciate in something like true perspective the momentous character of Dr. Davidson Black's first diagnosis.

The early recognition of the distinctive character of the human relics from these Pleistocene deposits eliminated many possibilities of doubtful interpretation, and prepared the way for the pregnant studies of the bearing of this great discovery on the general problem of human evolution, by which the late Sir Grafton Elliot Smith, Sir Arthur Keith, and others have made Peking man a crucial point in discussion. Much, however, as they have rested their argument for the course of evolution by which modern man has appeared upon indications afforded by distinctive or rudimentary characters in *Sinanthropus*, it will be gathered from the description of the new skulls by Prof. Weidenreich, and from his comparative study of their morphology, that the interpretation of *Sinanthropus* in terms of the evolutionary process now involves a change even more fundamental than anthropologists had contemplated.

Great significance in an evolutionary context has been attached to the combination of primitive and modern, if rudimentary, characters exhibited in Peking man. Prof. Weidenreich himself in recent studies has extended and given greater precision to this diversity of character, more especially in his investigations of the teeth and the conformation of the jaw, suggesting not only that in these characters does Peking man tend to approach modern man, but also indicating specifically a resemblance to certain of the modern Mongols. He now argues that this resemblance is further emphasized in the recent discoveries, while the broad and flat nasal bridge in one specimen, immediately, if tentatively, institutes a further point of resemblance to the Mongol in the possession of the characteristic, flat nose.

One of the most remarkable characters to which attention is directed by Prof. Weidenreich is the conformation of the brain, as shown in the endocranial cast ; but even more striking in this connexion is its remarkable size. In both male and female it is large for a primitive brain ; but in the male it is placed at approximately 1200 c.c., which is within no very distant range from the capacity of the modern brain, especially in the female. We need, then, feel no surprise at the cultural development of this early and primitive type of man as it is to be seen in the artefacts and in the evidence for the use of fire found in the cave of Choukoutien.

It is, however, when Prof. Weidenreich turns to the comparative study of *Sinanthropus* that his conclusions attain their most startling character. For here he now finds that the new evidence definitely places *Sinanthropus* at a lower stage in development than *Pithecanthropus*, the ape-man of Java, approximately in a geological sense his contemporary. Discussion, which hitherto has proceeded on the line that *Sinanthropus*, while standing in relation to *Pithecanthropus*, was definitely on the line of advance, is thus not a little confounded. On the other hand, Prof. Dubois, in his study of *Pithecanthropus* and early man in Java (see p. 294), offers a way out by removing *Pithecanthropus* from the human line and associating him with the gibbon, while in the recently discovered Solo man of Java—the *Javanthropus* to which Weidenreich and others see resemblances in Peking man—he sees, not a line leading to the Neanderthal stock destined to die out, but a member of a group, including Rhodesian and Wadjak man, which is on its way to becoming modern man in the person of the Australian aborigine.

Anthropologists, while congratulating Prof. Weidenreich on this great discovery made under the auspices of his laboratory, are deeply indebted to him for the dispatch with which he has placed at their disposal the new material for further discussion of this intricate and fascinating problem.

The Agricultural Research Council

THE Agricultural Research Council took over, on its formation in 1931, the functions of the Development Commissioners' Advisory Committee on Agricultural Research, and was charged with the duty of organizing and developing research so that the resources available for that purpose should be used to the utmost advantage. The wisdom with which that committee had developed and guided research had won for it the admiration of farmers and scientific investigators alike, particularly of those who could recall the backward position of Great Britain in agricultural research in the early years of this century. Research had so developed, however, that a more comprehensive body was needed for its guidance, one with powers such as that of forming committees and sub-committees which could bring the experience of specialists to bear on the various problems

While the Agricultural Research Council is analogous to the Medical Research Council, and to the Department of Scientific and Industrial Research, its administration is more complicated because it has not built up, nor does it control, its own research centres. The general relationship of the Agricultural Departments with the research institutes, university departments of agriculture and agricultural colleges remains unchanged, the Council giving criticism and advice on research programmes and grants; in 1934–35 the sum of £329,695 was included for research and advisory work in the estimates of the Agricultural Departments with appropriations in aid from the Development Fund. The Council has powers to initiate special services—a function eminently appropriate for a body having such a 'bird's-eye-view' of research and of the industry as a whole.

The second report of the Council* describes the continuation of a survey of agricultural research in Britain, but is devoted more particularly to those activities or institutions which have been the object of special inquiry during the period under review. Animal diseases continue to receive special attention, in accordance with a policy adopted by the Council early in its career—that of furthering work on certain diseases which might spread should the Government decide to encourage the live stock industry. The Council found that an increase in the number of trained investigators was one of the most urgent needs in this field of research, and took appropriate action.

Amongst the work of the specialist committees of the Animals Diseases Committee, that on braxy and braxy-like diseases may be noted; after reviewing the situation, it was decided that, as a foundation for further successful research in this field, more accurate information should be obtained on such questions as the incidence of infections of sheep by anærobic bacilli, and a special investigator was appointed to undertake a survey. As an example of research of special value to large tracts of the Empire, as well as to Britain, reference may be made to the work on sheep blow-flies at Bangor and at Aberdeen. Promising results have been obtained by studying separately the several factors involved in blow-fly attacks; thus, at Bangor, high humidity at the base of the wool was found to be one of the essentials for the eggs and larvæ of the fly, and work is in progress to investigate the conditions causing high humidity.

---

* Committee of the Privy Council for the Organisation and Development of Agricultural Research. Report of the Agricultural Research Council for the period October 1933—September 1935. (Cmd. 5293.) Pp. iv+130. (London: H.M. Stationery Office, 1936.) 2*s*. net.

The Agricultural Research Council performs an important function in serving as a link with other organizations interested in agricultural research. Thus, it was recognized early on that there was a common field in the study of human and animal nutrition in its bearing on health, and joint committees were formed with the Medical Research Council to investigate iodine deficiency and to co-ordinate work on tuberculosis in animals. Again, the Milk Marketing Board made a grant of £4,000 towards research on contagious abortion in cattle, and this was made to the Council.

As an example of the energetic action taken in consequence of the recommendations of its committees, the instance may be quoted of the report of the special committee on *Brucella abortus* infection, recommending that the Council should investigate this problem at a centre of its own, possessing an adequate area of land. The additional powers necessary to carry this into effect were promptly sought and secured.

The promptitude and vigour evident throughout this report emphasize the fact that the creation of the Agricultural Research Council was an event of the first importance for the science and practice of agriculture in Great Britain.

Peary: The Man and the Explorer

Peary
By William Herbert Hobbs. Pp. xv + 502 + 8 plates. (New York: The Macmillan Company, 1936.) 5 dollars.

THE appearance of yet another book on Peary would scarcely attract much attention were it not written by an author of international reputation, one who knew both Peary and Greenland. Prof. Hobbs gives a hint in his preface as to the reason for writing the book, namely, that Peary, for various reasons, has never had "the full acclaim that was his due". One of those reasons is the publication, in England and in America, of several books which, in no uncertain terms, pronounce that the claim of Peary to have reached the Pole was at least open to doubt, if not actually fraudulent. These books have had a vogue which must have deeply offended ardent supporters such as Prof. Hobbs. The real student of polar literature can have little regard for such books, and can only regret the existence of those writers to whom the phrase about bygones has no meaning at all, and who delight in resurrecting distasteful controversies of the past.

The present book, therefore, is at once a biography of a man and a refutation of the slurs that have been cast upon the claims of that man; yet the friendly critic must deplore that the author took upon himself that dual task when the first alone would have been more effective. The word "claim", introduced into the literature of polar exploration by the American Press and, be it admitted, by Peary himself, should never appear in such a book as this. Prof. Hobbs would probably answer that it was through the false claims of Dr. Cook to have reached the Pole a year earlier than Peary that the latter was put on the defensive; in other words, that it was not Peary who began the claiming.

It will be remembered that, owing to Peary's curious methods of navigation and the lack of witnesses on his final dash to the Pole in 1909, there was no decisive proof of his having been there, and his amazing rate of travel as soon as he left his last white companion gave his detractors the chance of beginning an undignified controversy. In the absence of documentary evidence, Peary's friends fell back on the argument that his character was such that he must have been where he said he had gone, upon which the scandalmongers began to ferret out his past in an endeavour to bring to light circumstances which might give a contrary colour to his character. In the opinion of the writer they failed to do so, and the verdict should be that Peary reached the vicinity of the Pole as he said he did, but it seems an odd way of arriving at a valuation of such a deed.

The announcement of a new life of Peary, therefore, gave hopes that it would so portray the man that the world at large would see without a doubt that his character did not permit of the kind of subterfuge of which he was accused. The picture begins with great promise: we are introduced to a very pleasant boy in a small town in Maine in the mid-seventies of last century. We read his delightful letters to his mother, about his work and his play, his associates and his plans for the future. At his college he was a very hard worker, as indeed he was throughout his life, and he won the praise and the friendship of his professor, who on one occasion described his standard with the queer phrase of "at least 100 per cent".

Devoted to the study of birds and becoming an expert taxidermist, he yet found time for winter sports, for horse-breaking and for writing poetry; all these in addition to a close attention to his more direct profession of surveying and civil engineering.

From his letters at this time, it is obvious that Peary was very ambitious, anxious to become outstanding in some way or another, a hard but cheerful worker and a pleasant companion. In spite of his love of the open air, we find him, after a short period as a surveyor, becoming a draughtsman in the Coast and Geodetic Survey, from which he rises by sheer merit, through a severely competitive examination, to a junior post in the Civil Engineering Corps of the United States Navy. At thirty years of age he has won his spurs as an engineer, making reconnaissance surveys for the projected canal in Nicaragua, which was afterwards abandoned in favour of the Panama site. It was at this period that his attention was turned to the polar regions by reading a paper on the inland ice of Greenland. With characteristic energy he followed up that lead by going to Greenland in 1886, alone, to try conclusions with the inland ice. With no one except a Danish companion, and by man-hauling their sledges, he managed to penetrate 100 miles on the ice-cap, just three years after Nordenskiöld's somewhat similar journey and two years before Nansen's famous crossing. For a man without experience it was a real feat, and on his return he was obviously wavering between his old love of surveying in the tropics and the new one of journeying in the Arctic.

It is at this stage in the book that the reader feels, with regret, that he has parted with the man and has met the explorer, that he will henceforth read the records of deeds as presented to the world but not of the thoughts and aims which led to the doing of those deeds.

Peary was a good writer and a prolific one, and his descriptive pieces are simple and effective. In his later books a certain egotism tends to assert itself, an egotism which, if read from private letters, might be a pleasant enough revelation of the man, but which, in a published narrative, is apt to jar. The author of this biography missed a great chance, if indeed it ever presented itself, by not continuing to quote from Peary's private correspondence. If, for example, he could have had access to his letters to his faithful and adventurous wife, we might have had a far truer picture of the man, of his hopes and his fears and his faith, than we can ever get from numerous quotations from his published books We believe that the child was really father of the man, and that somewhere there are private letters which reflect the writer faithfully as did his schoolboy letters to his mother. In this book, however, Peary becomes a public man henceforth, and we have to judge him from his own public account of himself. With this limitation, the book deals so faithfully and meticulously with his career that certain attributes of the great traveller stand out more and more clearly as it proceeds. The first is his indomitable determination and fierce energy. Not once but a dozen times, failure, even ignominious failure, faced him, yet he persisted in overcoming the obstacle. Whether it is a broken leg or a lost depot, a lack of funds or frost-bitten feet, he goes steadily on with his plans and his journeys. One can have nothing but admiration for his will to succeed, and his persistent pursuit of his self-appointed goal.

It is interesting, also, to trace Peary's gradual evolution as a polar traveller. He sampled, in succession, nearly all the possible modes of polar travel. Beginning with man-hauling with a white man, he goes on to dog-sledging with white men; then he gradually introduces Eskimo into his parties until finally he trusts almost entirely to the natives for transport. This argues an ability to adapt himself to conditions which was singularly lacking in many of the explorers of last century, and still more does it point to a treatment of the natives which, whatever its principles, was extraordinarily effective in winning sterling service.

Most of the great polar travellers have had an outstanding physique, and Peary was well in the forefront in this respect, as witness many incidents on his journeys. Even the fact that, in his final journey to the Pole, at fifty-three years of age, he rode on the sledges a great part of the time, does not detract from his record as a man who could outlast most of his fellows, as he did often enough in his younger days.

Peary's contributions to the technique of polar transport must have been many, and the only cause for hesitation in making a fuller tribute to him on this account is that in his later writings he invariably claimed that tribute in full measure himself, and in so doing, tended to dim his own reputation by insistence on what was his due.

The concluding chapters of the book, on the great Cook controversy, are, in the main, disappointing. The biographer admits that Peary handled the matter badly, that he was no match for Cook as a student of mass psychology. The reader who has read the book with sympathy will welcome that admission, but at the same time he will feel aghast that an explorer should ever have to study the psychology of a public to whom he tells his story. One is tempted to a base parody in suggesting that he who lives by the Press shall fall by the Press, and that brings us to the chief and, one hopes, sufficient excuse for the less pleasing aspects of Peary's life. He was, throughout his career, dependent on others for financing his expeditions; he was therefore living on his reputation, and forced by circumstance to bolster his own fame by his own writings, and to attack any force that tended to dim it. This book has not given us the real Peary—perhaps it was impossible to do so—but it gives us a clearer view than any other biography of a man whose name is much too great to be affected permanently by the snappings of minor detractors. F. DEBENHAM.

Butterflies of the Genus *Erebia*

Monograph of the Genus *Erebia*
By B. C. S. Warren. Pp. vii + 407 + 104 plates (London: British Museum (Natural History), 1936.)

IT might be difficult to decide whether a description of much of the taxonomic work that has been and still is being done as merely careless can be regarded as lenient or just. It certainly would not be harsh. In the latter half of the eighteenth century it was not unusual for one author to tackle the whole of the natural world, and, considering the magnitude of the task and the degree of development of knowledge at the time, the result was at least comprehensive. Since that time, our knowledge has grown to such an extent that the size of the taxonomic group with which any single author can hope to grapple effectively has become more and more restricted, and the superficial character of much of the work that has been done has added so much to the labour involved in revising even a single genus, that the systematist confronted with the classification of a suborder no larger than the Rhopalocera may well stand dismayed at the prospect.

It is not surprising, therefore, to find a volume of some 400 pages and more than 100 plates entirely devoted to a revision of the genus *Erebia*, which comprises some 69 known species, represented by 225 subspecies (geographical races), in addition to which there are 90 named forms and nearly 280 aberrations. The task of dealing with the nomenclature alone is no light one, as the number of names involved exceeds 900, nearly 600 of which are actually used to designate species, subspecies, forms and aberrations.

In directing attention to the need for this revision, Mr. Warren points out that of the many systematic works which include a treatment of *Erebia*, Dr. T. A. Chapman's paper is the only one in which any attempt is made to study the structural characters of all the known species of the genus.

The author puts forward the following five points, which in his opinion "cover the essentials of a genuine systematic work", and which have been aimed at in the production of this book:

> "(1) To supply definite proof, on an anatomical basis, of the real affinities of every hitherto described species, subspecies, form and aberration of *Erebia*; (2) to establish the correct use of every valid name, and to eliminate those that are only synonyms or homonyms; (3) to provide reliable data for the identification of species; (4) to treat the variation of each species comprehensively, but at the same time in as simple a manner as possible; (5) to give the distribution of each race accurately, but not in great detail, avoiding long distribution lists which would encumber the work without being of compensating value."

It is becoming more generally recognized that many of the distribution lists published are based on identifications of questionable accuracy, and that they unnecessarily increase the bulk and cost of production of any taxonomic work.

There is great need for more treatises like the volume under review, monographs in which every effort is made to state and display facts with simplicity, but with absolute precision. In the matter of illustrations, Mr. Warren has not confined himself to a single aspect of a subspecies or form, either in displaying the facies of the insect or the structure of the genitalia, and a study of the figures of different specimens of the same subspecies, even from the same locality, indicates that the book is fully, though not in any way too lavishly, illustrated. There has been a good deal of controversy in the past over the respective merits of photographs and drawings, particularly in connexion with the figuring of genitalia. Mr. Warren has taken the trouble so to dissect and photograph these structures that it has been possible to give a perfectly satisfactory picture, admirably arranged for purposes of comparison.

An interesting feature of this valuable and beautifully produced monograph is an original discussion on the androconial scale and its development in the genus *Erebia*, which it may be hoped will encourage students to make a special study of these scales in other butterflies.

Stellar Constitutions and Systems

Five Halley Lectures
Pp. iv +30 +32 +32 +18 +30. (Oxford : Clarendon Press ; London : Oxford University Press, 1936.) 8*s.* 6*d.* net.

THE Halley Lecture in the University of Oxford was founded by the late Henry Wilde, on the return of Halley's comet in 1910. The lecture is given annually on a subject connected with astronomy or terrestrial magnetism. The University by decree has defined astronomy to include astrophysics, and terrestrial magnetism to include "the physics of the external and internal parts of the terrestrial globe". Lectures under this benefaction have been given by many outstanding investigators in astronomy and geophysics. Most of the lectures have been of more than ephemeral value ; though many of them have afterwards been published in booklet form, most of them are now out of print.

It was a happy idea of the Savilian professor of astronomy to endeavour to form a permanent record of the lectures. Of those already delivered, which had been printed by the Oxford University Press, only five were available in sufficient numbers to justify binding in a single volume. It so happened that these five lectures were on astronomical subjects. The volume under review will be, it is hoped, the forerunner of similar volumes to appear in the future.

The lectures included in this volume comprise "The Rotation of the Galaxy", by Sir Arthur Eddington ; "The White Dwarf Stars", by Prof. E. A. Milne ; "The Composition of the Stars", by Prof. H. N. Russell ; "Red-Shifts in the Spectra of Nebulæ", by Dr. E. Hubble ; and "Dimensions and Structure of the Galaxy", by Dr. J. S. Plaskett. In reading through these lectures again, one cannot but be impressed by the able manner in which the subjects were dealt with, and unsolved problems were discussed.

The problem that was uppermost in the mind of Sir Arthur Eddington was the bearing of the rotation of the galaxy on the time-scale of stellar evolution "Geological time swallows up at least 1,500 million years ; we must allow a reasonable margin beyond that for the evolution of the solar system, say 3,000 million years altogether. The minimum requirement of our model system is that it will keep going for that time without collapse. Actually we are hard put to it to invent a galaxy with even this limited degree of permanence, which shall at the same time embody the main features of stellar motion and distribution enumerated on p. 6. As for those who dabble in the long time-scale of billions of years now fashionable (and I have to confess myself one of them) we must simply ignore them. Whatever the study of individual stars may bring forth in its favour, the evidence of galaxies and of systems of galaxies is dead against so leisurely a rate of progress. The problem of the galaxies is unapproachable except from the standpoint that the material universe is a much more evanescent affair". The lecture ended with these words : "Perhaps the lesson of the galaxies is to wake us from our dream of leisured evolution through billions of years. It is hard to credit our stellar system with so much age and endurance. It is more like a young man in a hurry". Since this lecture was delivered, astronomical opinion has been veering steadily in favour of the short time-scale for stellar evolution as opposed to the time of billions of years formerly current.

Prof. Milne discussed the white-dwarf stars and the nature of 'dense matter', sketched out his views on stellar evolution and described the relationship of novæ and of white dwarfs to his scheme. The recent appearance of two bright novæ, in addition to several fainter novæ, has given a great impetus to the study of the many complex problems that these interesting stars present. Milne's theory of the cause of a nova outburst, though not yet proved, still offers the most plausible working hypothesis. It may be mentioned that the large folding diagram (Fig. 3), which accompanies this lecture, has been omitted from the review copy of this volume. It is to be hoped that the omission is peculiar to this copy only, for without the diagram in question it is not possible to follow much of the argument.

In his lecture, Prof. Russell gave an admirable résumé of the present state of knowledge about the composition and physical conditions of the visible portions of the stars. The only stellar spectrum that has been studied in sufficient detail to permit a complete qualitative analysis is that of the sun. It is found that seven elements—magnesium, iron, silicon, sodium, potassium, calcium and aluminium—make up 96 per cent by weight of the solar metals, and these are the seven principal constituents of terrestrial rocks. The determination of the abundance of the non-metals is more difficult, as the lines in their spectra are faint and of very high excitation potential. The more conspicuous features of the distribution are a general decrease in abundance for the heavier elements and a greater abundance of elements of even atomic number than of elements of odd number. This relation has been noticed in terrestrial data also, and attributed in some way to the constitution of atomic nuclei. Another result of interest, confirmed in other ways, is that hydrogen is of the order of 1,000 times as abundant, atom for atom, in stellar atmospheres as all the metals together. The complicating factor in these investigations is that the maximum intensity of the lines of one element depends more often than not on the degree of ionization of another element. Further progress in the detailed quantitative analysis of stellar atmospheres is dependent upon the more detailed investigation of stellar spectra. The great 200-inch telescope, with a focal length in the Coudé form of about 500 feet, will permit a more complete investigation of the spectra of the brighter stars than has hitherto been possible.

Dr. Hubble's lecture dealt with a problem the solution of which must also await the completion of the 200-inch telescope—the interpretation of the red-shifts in the spectra of the extra-galactic nebulæ. "This telescope should penetrate to distances where the effects of red-shifts are so great that the requisite data will lie well above the threshold [of the photographic plate]. Such data will afford critical empirical tests of the interpretation of red-shifts as representing actual motion, and will establish the form of the velocity-distance relation in regions where the velocities, whether real or apparent, are considerable factions of the velocity of light". The method of investigation is to examine the apparent departure of the distribution of the extra-galactic systems from statistical uniformity. This apparent departure from a uniform distribution is attributed to the reddening of the light from the systems, which increases with distance. The effect to be expected will differ according to whether the reddening is, or is not, interpreted as a velocity effect.

The remaining lecture, the most recent of the lectures on an astronomical subject, was given by Dr. J. S. Plaskett in 1935, and dealt with the present state of knowledge about the dimensions and structure of the galaxy. During the past twenty-five years there have been considerable changes in current ideas as to the dimensions of the galaxy. Eddington, in the first of the lectures in this book, when referring to some dynamical investigations that he made in 1913–15, remarks: "But when I turn to the efforts I then made to fit the theory to the observed properties of the system, it is like a glimpse of the middle ages. Is it possible that only fifteen years ago we thought the stellar universe was like that! With some misgiving I found I must place the sun at least 500 parsecs away from the centre of the system; but I did not expect to be believed. Nowadays 7,000 parsecs is the minimum estimate".

The great expansion in the size of the system followed from Shapley's application of the luminosity-period relationship for the Cepheid variables to the estimation of the distances of the globular clusters. He gave the system a diameter of 260,000 light-years. The diameter of the largest known external systems, the Andromeda nebula, was later estimated by Hubble to be about 40,000 light-years, so that there seemed to be a great disparity in size between the galaxy and the external systems. Subsequent investigation has tended progressively to reduce this disparity. The revision of the zero-point of the Cepheid period-luminosity curve, and allowance for the presence of absorbing material within the system, which dims the light of distant stars and causes distances depending on any luminosity method to be overestimated, has reduced the dimensions of the galactic system. The distance from the sun to the centre of the galaxy derived dynamically from investigations of the rotation of the galaxy is now in good agreement with that deduced from the distribution of the globular clusters—about 10,000 parsecs or 32,000 light-years. The diameter of the system is of the order of 100,000 light-years.

Concurrently with the reduction in the size of our own system, the extimated dimensions of the Andromeda nebula have been enlarged. Hubble, in 1932, identified 140 nebulous objects in and near the Andromeda nebula as globular clusters, dynamically connected with the system. Many of these were outside the limits of the system shown on long-exposure photographs. In 1933, Stebbins and Whitford, from photo-electric measures, showed that faint nebulosity extended to much greater distances than had been supposed. These investigations have combined in showing that there is no great difference in size between the Galaxy and the Andromeda nebula. Dr. Plaskett ends his lecture, however, with a note of caution: "While the dimensions, structure and dynamical organization of the Galaxy have been here fairly definitely stated, the proposed model must be considered only as a preliminary attempt at the solution of this difficult but very important astronomical problem. In view of the changes that have occurred in our conceptions of the Galaxy during the past twenty years, one would be very rash to predict that even approximate finality had been reached. All that can safely be said at present is that the concept developed has a certain unity, completeness, and probability, and it can only be hoped that it makes a useful introduction to more complete knowledge".

H. S. J.

Modern Sociologists

(1) Comte: the Founder of Sociology. By F. S. Marvin. Pp. 216.
(2) Veblen. By J. A. Hobson. Pp. 227.
(London: Chapman and Hall, Ltd., 1936.) 6*s*. net each.

(1) Mr. Marvin's "Comte", notwithstanding the brevity of treatment imposed by the limitations of the series of which it forms part, is one of the best and most lucid expositions of the doctrines of the founder of 'sociology' extant. Its merits, however, are not confined solely to its treatment of the positive philosophy and the religion of humanity as originally formulated. The author, having in mind the aim of the series to bring the principles of sociological thinkers into relation with the problems of to-day, has essayed the by no means easy task of evaluating the position of Comtian theories at the present time. In so doing, Mr. Marvin has analysed current trends of modern society in thought, in scientific discovery, and in social development, with an acute perception and a sanity of judgment, which not only provide an efficient antidote to current moods of superficial pessimism, but also convey a gospel to scientific workers and practical sociologists.

(2) Veblen is a thinker of a very different order from Comte; and notwithstanding Mr. Hobson's acute and sympathetic analysis of his work, it is difficult to evade the conclusion that his sociological doctrines were little more than a sublimation of personal experience. His early life on a Middle-West farm and in Chicago at the close of the nineteenth century, when the corrupting influence of financial interests was at its height, fundamentally affected his reading of history and his view of the development of society. His interpretation of the evidence of anthropology, upon which much stress is laid by his admirers in the United States, is superficial and lacking in understanding. This view would probably not meet with the assent of the author of this exposition. The brief introductory sketch of the events of Veblen's life given here needs revision as to its dating.

Über Katalyse und Katalysatoren in Chemie und Biologie

Von Alwin Mittasch. Pp. vii + 65. (Berlin: Julius Springer, 1936) 3.60 gold marks.

A lifetime's work on technical catalysts lies behind this little pamphlet. While Haber proposed and outlined experimentally the idea of nitrogen fixation, and Bosch developed the apparatus for it, Mittasch solved one of the main practical difficulties attached to the process, by the discovery of an iron catalyst of a certain composition.

Few people know more about technical catalysts than does the author; much of the existing knowledge has grown up under his direction and has never been published. It is astonishing how little all this important work has contributed to the elucidation of the principles of catalytic action. The pamphlet gives no scientific views on this subject. Besides reviewing the various aspects of chemical catalysis, it surveys a great number of biological phenomena in which small quantities of substance have big effects: the action of enzymes, poisons, heredity are all spun together in a web of loose analogies. Some of the points referred to are of quite recent date and impress upon the reader the wideness of the author's knowledge. This factual survey may be of some use, even though there is no idea underlying it.

One is reminded of Gudden and Pohl's treatise on photo-electric conductivity which, when introducing the chapter on selenium, notes that this particular field is most obscure owing to the great amount of technical work done in it. It seems that technical research conducted under an employer's authority, in an atmosphere of secrecy, is far less effective in discovering the principles involved in a process than pure research open to world-wide discussion.

M. Polanyi.

Witches and Warlocks

By Philip W. Sergeant. Pp. 290 + 15 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1936.) 12*s*. 6*d*.

Dr. Margaret Murray's study of witchcraft in western Europe, which revived the theory of a Dianic cult and brought its manifestations into relation with modern ideas on the character of primitive religion, gave an orientation to the numerous studies of witchcraft which followed, and demanded from her imitators and successors something more than descriptive narrative to justify publication. Mr. Sergeant's claim to serious attention lies in his careful and detailed analysis of the evidence in the cases of the Lancashire witches, and the part played by the Mathers and others in the persecution of the Salem witches in America, as well as in his account of the Elizabethan Dr. Dee and his evil genius Kelly. On the theoretical side he is not equally happy. His knowledge of primitive religion is scarcely adequate to the demand—his reference to totemism seems particularly wide of the mark—nor does his knowledge of the literature of that subject appear to be extensive.

Aluminium-Legierungen

Von A. Grutzner. Unter Mitarbeit von G. Apel. Teil 1. Patentsammlung geordnet nach Legierungssystemen. Pp. vii + 342. 35 gold marks. Teil 2. Patentsammlung. Nebst einem Markenverzeichnis bekannter Aluminium-legierungen, von Prof. Dr. A. von Zeerleder. Pp. iii + 343–868. (Zugleich Anhang zu Aluminium Teil A in Gmelins Handbuch der anorganischen Chemie, Achte Auflage, herausgegeben von der Deutschen Chemischen Gesellschaft.) (Berlin: Verlag Chemie, G.m.b.H., 1936.) 54 gold marks. (Ausland preis, 40 50 gold marks.)

The alloys of aluminium are so numerous that a complete table of them has been compiled, which runs to more than 800 pages and is issued in two parts. The table facilitates reference to the patent literature, and a further useful feature is a supplementary list of all the known alloys of the metal in the alphabetical (or numerical) order of their trade names, together with the names of patent holders and percentage compositions.

The New Discovery of Three Skulls of *Sinanthropus pekinensis*

By Dr. Franz Weidenreich,

Visiting Professor of Anatomy, Peiping Union Medical College, and Honorary Director of the Cenozoic Research Laboratory, National Geological Survey of China

FOLLOWING the recovery of several fragments of a very small adult skull of *Sinanthropus* from Locus I (Locality 1) in the latter part of our spring field season at Choukoutien, we had the good fortune during the fall season of this year to unearth three additional more or less well-preserved skulls, two of which were recovered on one day. All three skulls belong to adult individuals. The skull recovered first, and designated as Skull I of Locus L (Fig. 1), is the largest, with a cranial capacity of approximately 1,200 c.c. and with its coronal and sagittal sutures partly fused. The second skull (Skull II of Locus L, Fig. 2) is the smallest of the group, with a cranial capacity not higher than 1,050 c.c., and its coronal, sagittal and lambdoid sutures fused. This skull shows a clear indication of the persistence of a metopic suture. The third skull (Skull III of Locus L, Fig. 3) is smaller than Skull I, but larger than Skull II. The cranial capacity of Skull III is approximately 1,100 c.c. Although all the sutures of this skull are still patent, yet other characteristic features make it evident that we are concerned with a young adult individual. Parts of the face are preserved in all three skulls ; thus, in Skull III both nasal bones and the entire lateral border of the orbit in complete connexion with the brain case ; in Skull II the frontal process of the maxilla, the lower border of the orbit, the cheek-bone and fragments of the alveolar process of the upper jaw with palate and ten teeth *in situ* (premolars and molars), which, however, are not connected with the skull. Belonging to Skull I are several teeth only. In addition, we have a great number of very small fragments apparently pertaining to the face, yet it is rather doubtful whether it will be possible to undertake even a partial reconstruction.

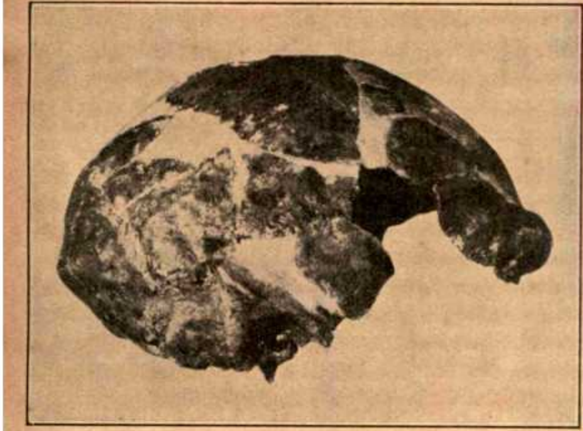

Fig. 1.

Sinanthropus pekinensis, Skull I, Locus L, adult male. Norma lateralis, right side. × ⅓.

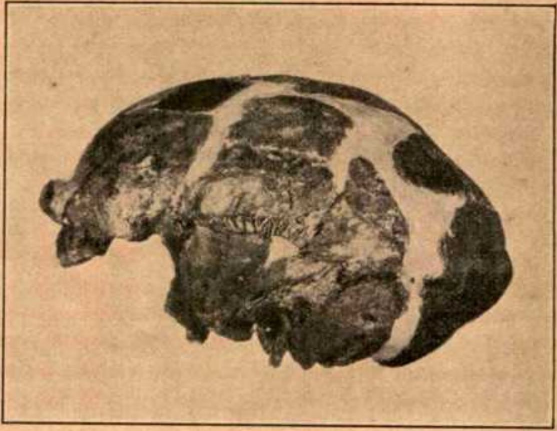

Fig. 2.

Sinanthropus pekinensis, Skull II, Locus L, adult female. Norma lateralis, left side. × ⅓.

As has been noted in the case of all teeth of *Sinanthropus* recovered hitherto, it is also true for *Sinanthropus* Skulls I and II, namely, that they possess a large and a small type of teeth. I had previously arrived at the conclusion that the large teeth may belong to male individuals and the small to female individuals. This assumption has been confirmed by the fact that the large type of teeth pertain to the bigger skull (Skull I) while the small type of teeth is to be found in the small skull (Skull II, Fig. 4). Thus it seems quite certain that the latter represents the skull of a female individual, and the former that of a male individual.

Parts of the base are missing in all three skulls. Skull I is the most defective, with only the right temporal bone being preserved. In Skull II both temporal bones are present, but a great part of the supraorbital region is broken off. Skull III is the most complete one ; the entire occipital bone with the posterior border of the foramen magnum is preserved. However, the right temporal bone has been lost.

All three skulls have the same appearance as Skull I of Locus E described by Davidson Black (1931). However, since this skull belongs to a child of eight–nine years (cf. Weidenreich, 1935), the characteristics of the *Sinanthropus* type are much more pronounced in the recently recovered skulls such as, for example, the size and thickness of the supraorbital ridges and the occipital torus, the crest of the vertex and the muscle markings of the temporal bone. The greatest transversal diameter of all three skulls is represented by the biauricular breadth with the breadth decreasing gradually above the ear aperture. The accompanying table (see below) shows the results derived from the more essential skull measurements in comparison with those available for *Pithecanthropus*, Neanderthal and recent man. The measurements 8–13 giving the corresponding ratios reveal that *Sinanthropus* as a whole occupies the lowest place in the order of all hominids in regard to those peculiarities which determine its position in the line of evolution. This is particularly true for Skull II of Locus L, while Skull I of Locus L in part falls within the range of variations of the Neanderthal group. However, Skull II apparently is even lower than *Pithecanthropus*, the difference being that the *Sinanthropus* skull shows a more pronounced frontal tuber than *Pithecanthropus*, the entire forehead of which is flattened. The smallness and lowness of *Sinanthropus* Skull II is all the more remarkable since the skull fragments recovered last summer and considered to pertain to an adult individual are still smaller in dimensions than the respective parts of Skull II of Locus L and *Pithecanthropus* (cf. Weidenreich, 1937).

TABLE*

	Sinanthropus				*Pithe-can-thropus*[2]	Neanderthal group				Recent man[3]	Chim-pan-zee[3]

* The figures in italic type represent limiting values of the individual groups, with the exception of recent man and chimpanzee. Measurements of Locus E skull not considered in limiting values on account of its immaturity.

[1] After Davidson Black's figures, but the position of inion has been rectified. [2] Reconstruction after Weinert. [3] Average figures of all races.

Since the character of a type is not always defined by the general shape only but also by the feature of details, it deserves special attention here that the new *Sinanthropus* skulls completely agree with Skull I of Locus E in this respect. This is true, for example, in respect to the position and form of the ear aperture—with the exception of the cleft of the tympanic part of the temporal bone which is distinctly an infantile character in recent man and is missing in all adult *Sinanthropus* skulls—and in regard to the smallness and form of the mastoid process, as also the very narrow space between the temporal lines on both sides.

As to the face, the parts preserved in Skulls II and III yield a rather good idea of the general structure, at least so far as the upper parts are concerned. The nasal bridge is broad and flat (the index of the inter-orbital breadth is 29·8 average); Neanderthal group: Spy I, 28·8; Rhodesia, 28·6; La Chapelle aux Saints, 26·8; recent man, 24·3 (average). There is no groove between the root of the nose and the forehead. The orbit is very low (orbital index of Skull III, 77·2; Rhodesia man, 75·5; La Chapelle, 81·9; Gibraltar, 91·1; recent Australian, 78·8 (average male); the lateral border recedes backwards below the frontal zygomatic suture. The lacrimal fossa is missing in all skulls. The orbit is deep and the superior orbital fissure very small. The cheek bone is remarkably high, as high as that of the Rhodesia skull. A canine fossa does not exist and the anterior surface of the frontal process of the maxilla is slightly convex and not depressed as in recent man. The upper jaw, therefore, must have projected considerably. The palate is broad and high.

Earlier (1935) I was able to demonstrate that a close connexion between *Sinanthropus* and certain groups of the present Mongol race could be assumed. The occurrence of the so-called 'torus mandibularis' on the inner side of the mandible of some of the *Sinanthropus* jaws as well as on those of recent Mongols, especially Eskimos and Lapps, and furthermore the occurrence of shovel-shaped medial and lateral upper incisors in *Sinanthropus*, as also in modern Mongols, indicate some direct relationship between Peking man and the Mongol group of recent mankind. Whether or not the broad and flat nose of *Sinanthropus* points to the same direction I do as yet not venture to state. However, in addition, there is another conspicuous feature which, I believe, serves as further evidence for the assumption of such a special relationship. All three adult skulls show a large 'inca-bone' (*os epactale*) which, it is true, is not confined to the ancient Peruvian natives as the name suggests but also occurs in other races of to-day. However, it is much more frequent in the American Indian and Mongol group (up to 7·8 per cent) than in the latter (up to 2 per cent).

One of the most striking features revealed by the recently recovered skulls is met with in the endocranial casts. I had previously remarked (1936) that, in the *Sinanthropus* Skull of Locus D (Black's Skull II), the pole of the frontal lobe of the brain projects far outward and continues with a sharp keel downward (orbital rostrum). This peculiarity is especially pronounced in Skull III, and in somewhat different manner also in Skulls I and II of Locus L; in the latter two the keel is not so sharp, but nevertheless it projects downward in a very straight line. In this respect the endocast of Skull III resembles that of a chimpanzee, while Skulls I and II resemble more that of a gorilla. At any rate, all endocasts differ distinctly in this respect from those of Neanderthal man or *Pithecanthropus*. Skulls II and III are furthermore remarkable for the existence of an astonishingly low and narrow temporal lobe, a condition which I had pointed out when describing the temporal bone of Skull III of Locus H (1936 *a*).

As to the relation to *Pithecanthropus*, *Sinanthropus* Skull II of Locus L, together with the fragmentary *Sinanthropus* of Locus I mentioned above, prove incontestably that there is no appreciable difference between *Pithecanthropus* and *Sinanthropus* so far as the general shape and the lowness of the skull caps are concerned. Since it has been assumed that these two *Sinanthropus* skulls belong to female individuals, it is very probable that *Pithecanthropus* also belongs to the same sex, a probability which had already been pointed out by E. Dubois and Hrdlička. The *Sinanthropus* skulls differ from *Pithecanthropus* by only two characters, namely, in that the frontal bone proper is more vaulted in *Sinanthropus*, although its inclination to the glabella-inion line is distinctly more pronounced than in *Pithecanthropus* (compare measurements 10 and 11 of table). Furthermore, the supraorbital ridges of *Sinanthropus* are separated from the forehead by a really broad furrow, while in *Pithecanthropus* they continue gradually to the brow. The latter phenomenon, however, seems to have some connexion with the formation of the frontal air-sinuses. In *Pithecanthropus* these sinuses are conspicuously large and extend far lateralward over the roof of the orbit, whereas in all cases in *Sinanthropus* they are very small and closely confined to the interorbital region. I consider this appearance in the case of *Sinanthropus* as an indication of its being more primitive than *Pithecanthropus*, and the latter, in spite of the absence of prominent frontal tubera, as a more advanced type of hominid.

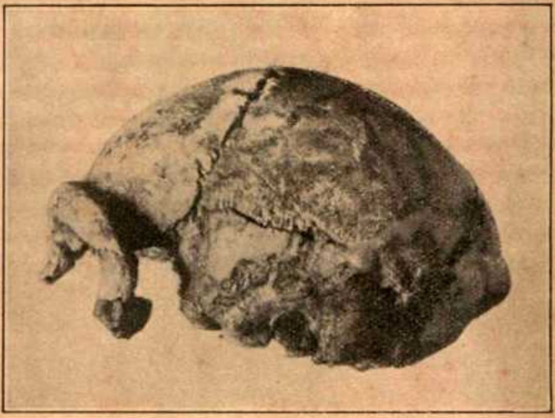

Fig. 3.

Sinanthropus pekinensis, SKULL III, LOCUS L, ADULT MALE (YOUNG). NORMA LATERALIS, LEFT SIDE. × ⅓.

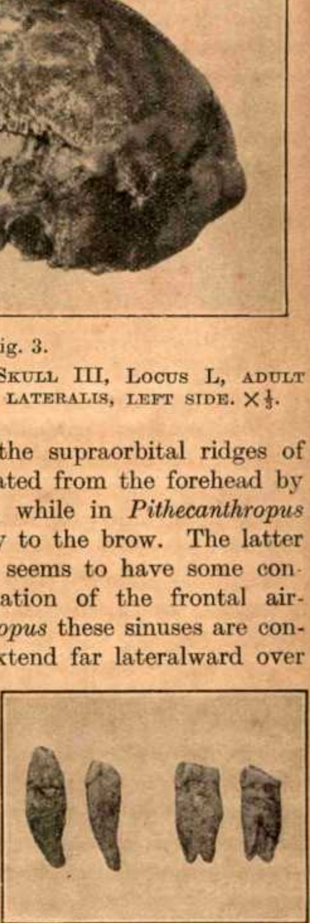

Fig. 4.

UPPER CANINES AND UPPER FIRST PREMOLARS OF MALE SKULL I AND FEMALE SKULL II. × ½. FROM LEFT TO RIGHT: CANINE, SKULL I, CANINE, SKULL II; PREMOLAR, SKULL I, PREMOLAR, SKULL II.

Another important fact is disclosed by *Sinanthropus* Skull I of Locus L. This skull is not only the largest of all *Sinanthropus* skulls recovered hitherto (*c.* 1,200 c.c.) but at the same time also the highest. Although its general structure and essential details show the same characters as the lowest Skull II of Locus L, yet its greater cranial capacity approaches closely the more primitive representatives of the Neanderthal group as revealed by the table. I had earlier (1936 *b*) assumed that there must be some relation between *Pithecanthropus* and *Javanthropus soloensis*, the latter resembling the former in several primitive characters. On the other hand, there is no doubt that *Javanthropus* has many peculiarities in common with *Sinanthropus*, as recently demonstrated by C. U. Ariëns Kappers (1936) in regard to the endocasts. I should not be surprised if *Pithecanthropus* at some future date should be found to represent nothing else but a special female type of *Javanthropus*. Since *Javanthropus* as a whole represents a very primitive form of Neanderthal man, the line linking *Pithecanthropus* and *Sinanthropus*, respectively through *Javanthropus* or Neanderthal man, to recent man is continuous. The fact that there may be certain racial deviations does not matter greatly, since the determining factor does not depend on relatively minute differences but on the main course of human development itself.

The Structure of Liquids

THE Edinburgh discussion of the Faraday Society on September 24–26 on the subject of "The Structure of Liquids and Solutions" was a particularly successful and satisfactory conference. The choice of subject had been very happily timed. The theory of the structure of liquids, which has been in recent years approached from a number of different angles, appears now to have reached a stage in which a larger synthesis is possible, and the bringing together in Edinburgh of many of those who have most notably contributed to these theories has markedly helped towards such a synthesis.

The earlier approach to the theory of liquid structure was almost inevitably an extension of the theory of gases, and the continuity of the two states as established theoretically by Van der Waals seemed to justify this treatment. This approach, however, had led to but little advance in explaining most of the characteristic properties of liquids. A recent tendency, on the other hand, which has taken its origin in the X-ray studies of liquid structure, has been to treat the liquid as more closely analogous to the crystalline solid. This has proved a much more fruitful line of advance for ordinary liquids, that is for liquids at temperatures far removed from their critical temperatures.

The chief difference between liquids and crystals is that in liquids we have irregularity of position and orientation of molecules in the place of the regularity of the crystal arrangement. This irregularity is limited by the general condition that in liquids the molecules are approximately close-packed. A great advance in the study of liquids is the development of the precise method of defining the molecular or atomic *configuration* of a liquid under any conditions. This has been achieved by means of the distribution function $g(r)$ of Debye and Prins, which gives the probability of finding a molecule at every distance from an arbitrarily chosen one (see Fig. 1). The peaks of the distribution function correspond to the perfect co-ordination spheres surrounding atoms in a regular crystal structure, and Prins has suggested that one can be derived from the other by considering each co-ordination sphere of mean radius r_k and

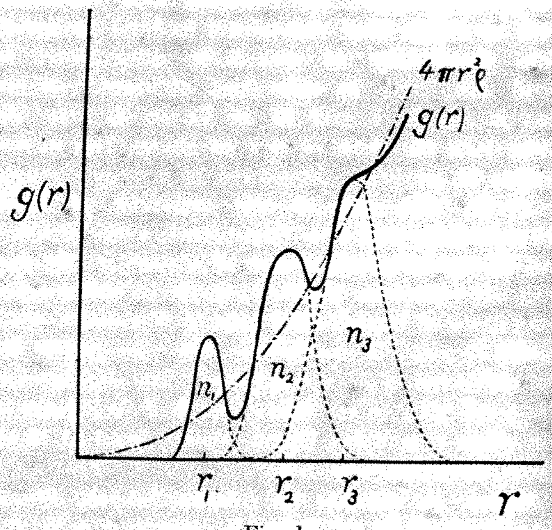

Fig. 1.

containing n_k molecules to be smeared out by a form of error function, so that the distribution function may be written

$$g(r) = \sum_k g_k(r) = \sum \frac{n_k}{4\pi r_k^2} \sqrt{\frac{c}{r_k}}\, e^{-\frac{1}{\lambda^2}\left(\frac{r-r_k}{kT}\right)^2}$$

Bernal has attempted to apply this idea to the conditions of equilibrium of liquid structures. Any possible configuration of the liquid can be defined by a distribution function depending on only three variables, the average number N of close neighbours of any molecule, the mean distance R of these neighbours, and the variability of this distance, which is equivalent to the measure of the irregularity of the structure. Of all configurations defined in this way, that one will be stable for which each free energy is a minimum for any variations of N, R and λ With rise in temperature the values giving such a minimum will change, the co-ordination number in general falling and the irregularity increasing. We may think of the change of configuration of a liquid on heating as equivalent not only to change in the number of excited vibrations, as occurs in a crystal, but more to the transformation of one crystalline phase into another. In a liquid there is an infinite sequence of different configurations, while the condition that the free energy remains constant for any change of phase becomes the general condition of minimum free energy for all configurations. The increasing potential energy on passing from a low-temperature to a high-temperature configuration consequently gives to liquids a term in the specific heat which does not exist in the crystalline solid, and makes the specific heat of liquids at low temperatures larger than can be explained by any theory based on the excitation of degrees of freedom alone.

Prof. F. London, who presented an admirable introductory paper on "The Nature of the Forces acting between Atoms and Molecules in Liquids", discussed particularly the structure of what should be the ideal, but what is actually the most anomalous of liquids, liquid helium. Here the importance of zero point energy is so great that the minimum of potential energy has little effect in fixing the configuration of the liquid, so that each atom has only four neighbours instead of the twelve that occur in normal liquids. E. Bartholomé and A. Eucken and L Brillouin dealt with the theory of specific heats of liquids. So far, however, no quantitative theory has been successfully evolved to cover either the behaviour of liquids at very low temperatures or near the critical point, where the general theory indicated above would require considerable modification.

The crucial question of whether the liquid and crystalline states form a continuum in the same sense as liquid and gaseous states was much discussed. J. Frenkel claimed that such a continuum exists, from theoretical considerations, and believes that the transition between crystals and liquids can only be achieved at low temperatures under large negative pressures. F. Simon, on the basis of experimental evidence, considers that, if it occurs at all, it is only at high temperatures and positive pressures. According to Bernal, on the other hand, for purely geometrical reasons no intermediate state should be possible. This question, however, is probably premature, as the theory is not sufficiently advanced and the experimental conditions very difficult to achieve.

Several very notable semi-empirical generalizations on the properties of liquids were given to the conference. According to Bauer and Magat, it appears that a number of properties of liquids, notably their specific volume, surface tension and specific heat, can all be plotted on the same curves, if the temperature ordinate be taken as $\theta = (T - T_F)/(T_C - T_F)$, where T_C and T_F are the critical and melting temperatures respectively. These generalizations would seem to imply that the structures of different liquids resemble one another far more than do the structures of corresponding crystals; they would almost merit the sweeping statement *that there is only one liquid state*. This requires to be qualified, however, by the possibility that for all the liquids investigated, except water, which is as usual anomalous, the molecules or molecular groups are in a state of free rotation, and that consequently the generalization applies only to assemblages of effectively spherical units. Liquids with highly asymmetrical molecules would tend towards the greater regularity of the liquid crystalline state. Hudleston has shown that similar regularities occur in the compressibilities of liquids, and that they can be referred to a very simple semi-empirical law, while A. G. Ward, by considering the constant B in the viscosity temperature relation,

$$\eta = A e^{B/RT},$$

has shown that it is closely related to the latent heat of melting and the general physical type of the liquid.

A new method of investigating the properties of liquids, the measurement of absorption of ultrasonic waves studied by M. P. Biquard and J. Errera, has led until now to highly anomalous results. This absorption is found to be larger, and sometimes as as much as a thousand times larger, than that which would be expected under existing theories, and this suggests very forcibly that there are some phenomena in liquids, possibly related to changes of configuration, that have an appreciable characteristic time of the order of a millionth of a second.

The second part of the conference, devoted to solutions, is more difficult to summarize because here general principles were not so much in evidence. Prof. J. H. Hildebrand, in his introductory paper, laid stress on the need of greater precision in defining the nature of the intermolecular forces in solutions and the meaning of association. In particular he emphasized the much greater importance of the extremely active hydrogen and hydroxyl bonds in liquids compared with the less localized dipole forces.

There was considerable discussion as to the validity of Raoult's law for liquid mixtures and in the changes of entropy on solution, but the general impression, well expressed in Prof. J. Kendall's paper, was that in this field anomalies are more apparent than regularities. The structure of liquids themselves being so complex, that of solutions, except dilute solutions of very simple substances, must be far more so. There are so many factors, in the size and shape of the molecules, in the existence of active association centres and in the possibility of formation of limited or indefinite clusters, that it is only in groups of fairly closely related substances in the same solvent that regularities may be expected. Thus, for example, J. A. V. Butler has shown that a series of aliphatic alcohols dissolved in water have heats of solution which can be calculated additively from the number of carbon atoms they contain, and that the entropy of solution is a linear function of the heat of solution.

The value of new methods, such as those of density and magnetic susceptibility, in studying solutions, was brought out in many papers. Perhaps the most important was the study of the infra-red absorption of solutions carried out by J. Errera. He was able to show, for example, by a change of frequency in absorption in a solution of alcohol in carbon tetrachloride, that the alcohol molecules are appreciably associated in pairs at concentrations so low as 0·1 mol.

With the analogous use of Raman spectra, it should be possible to determine in liquids and liquid mixtures the degree and kind of molecular association, because whenever this association is a close one it will affect both infra-red and Raman spectra. It may even be possible in some cases to calculate the intermolecular potentials from some form of model structure, as proposed by Magat. But so far, except in the case of water, where quantitative agreement can be got, the results are only qualitative. It is clear, however, that the time has come to begin attack on the problems of liquids and solutions on the basis of molecular theory, and that all this means we shall be able to explain many, at any rate, of the difficulties that have remained unresolved by the application of classical methods in this field.

The Edinburgh discussion of the Faraday Society showed the beginning of this process, and it is to be hoped that if the lead there given is followed up, the structure of liquids will no longer remain the most unsatisfactory part of molecular physics.

Obituary Notices

Mr. P. A. Ellis Richards

BY the death on December 22 last of Percy Andrew Ellis Richards at the age of sixty-eight years, Great Britain lost one of its foremost public analysts, chemistry one of its most devoted servants, and the teaching profession one who graced it throughout a long and successful career. Born in 1868, and educated at St. Paul's School and King's College, London, he studied analytical chemistry under the late Prof. C. W. Heaton, whom he succeeded as lecturer in chemistry at Charing Cross Hospital. After the passing of his chief, he set up in practice as a consulting and analytical chemist, and was soon appointed public analyst for the parish of St. Martin-in-the-Fields, continuing his work in this capacity when his parish was joined with others to form the City of Westminster. Not long after, he was appointed to a similar post at Hammersmith, and held both until a few years ago, when failing health compelled his retirement.

During his analytical career, Richards carried out work upon the 'facing' of rice, on vinegar, and on preservatives in imported meat for the Local Government Board—now the Ministry of Health. He also served on the Departmental Committee on Preservatives and Colouring Matters in Food appointed by the Minister of Health in 1923, and on the Departmental Committee on 'Improvers' in Flour in 1925. He contributed numerous papers to scientific journals upon topics not only in his own sphere, but also upon other subjects such as the saline waters of Boston Spa and of Salsomaggiore, ancient Russian and Irish bog oak, the determination of platinum in alloys, and the determination of iron in animal organs in connexion with researches on pernicious anæmia.

Richards' merits as a teacher were no less than those as an analyst. Very many past students of Charing Cross and the Royal Dental Hospitals and of Queen's College, London, will recall with gratitude his gentle and painstaking manner no less than his powers of lucid exposition of difficult points in chemistry and metallurgy. He was the author of what is perhaps the best-known work on practical chemistry for medical students.

Richards was unstinting in the service he gave to chemistry. He was a fellow of the Chemical Society, a fellow of the Institute of Chemistry and a member of the Society of Public Analysts. He served the Institute for two periods of four years as a member of Council and for another four-year period as examiner in food and drugs. He was for seventeen years honorary secretary to the Society of Public Analysts and for two years its president.

A marked ability in matters financial was put to very good use as bursar of Queen's College, treasurer of the Royal Dental Hospital and sometime auditor to the Institute of Chemistry. For many years honorary analyst to Charing Cross Hospital, his marked interest and ability in medical chemistry and toxicology led to his being consulted in some famous cases.

During Richards' life scientific history has been made. From the beginnings of the Periodic Law which his early days witnessed, we have progressed as far as the expansion of the Periodic Table to include elements that Nature has apparently never made, but which her creature man has. To readers of NATURE the enormous growth of chemistry within the past forty years or so will need no stressing, nor will the recent coming into its own of Richards' side of it—analytical chemistry. This part of the science, once almost contemned, has been called upon successfully to elucidate problems ranging from the detection of elements in far-off worlds to the fixing of the approximate age of our own world.

Science had in Richards a loyal and energetic servant who contributed his due, and more, to its advancement; it mourns one who at the height of his powers was laid aside, and to his infinite regret had to look on while work to which he had devoted his life was being brought to a successful conclusion. His interest in science never flagged during his years of failing health, and it afforded him keen pleasure to witness the ultimate glorious success of the branch of it which he had made his own.

F. W. EDWARDS.

Mr. L. de Whalley

MR. LAWRENCE DE WHALLEY, formerly chief chemist of Messrs. Tate and Lyle, died at his home at Orpington on January 9 aged eighty-three years. He was born and educated in Lancashire, and was successful in obtaining a scholarship at the Royal School of Mines, London, where he worked under Huxley, Valentin and Edward Frankland, whose honorary assistant he became. He attended Prof. Seeley's geological excursions and was keenly interested in Nature and natural history, an interest he never forsook. At the University of London he obtained his B.Sc. with honours in physics, and was one of the original members both of the Physical Society and of the Society of Chemical Industry, being honoured at the latter's jubilee in 1931, when he was presented with its memorial plaque. He was also a fellow of the Institute of Chemistry and of the Chemical Society, a member of the Society of Public Analysts and one of the founders of the Chemical Club. His earliest appointment was at the works of Messrs. Forbes, Abbot and Leonard, now part of the South Metropolitan Gas Co. In 1890 he joined his two brothers-in-law, the late John Joseph Eastick and Charles E. Eastick, later managing director of Martineaus, Ltd., at the refinery of Messrs. Abram Lyle and Sons at Plaistow Wharf, Victoria Docks, London, and became chief chemist when J. J. Eastick left to take up an appointment in Australia. This position he held until his retirement in 1930.

De Whalley was a great authority on matters of sugar refining, particularly in regard to bone charcoal, and was one of the first to see the advantages of using kieselguhr for sugar filtration. He introduced the affination process at Plaistow Wharf, and greatly improved the manufacture of golden syrup. He originated the iron test for sugar liquors and the sulphide stain method for sulphites, and was one of the first to adopt Molisch's alpha-naphthol test. He attended many international conferences on sugar analysis both in Great Britain and on the Continent and visited many foreign countries and refineries in regard to process developments. He was chairman of the Congress of Sugar Chemists (The Raffinose Conference) at the Sugar Institute in Berlin in 1910, when he contributed some work on raffinose in raw beet sugar. During the Great War, he was a representative at the Royal Commission on Sugar Supply; in August last he attended the meeting of the International Commission for Uniform Methods of Sugar Analysis.

De Whalley was a good mathematician and linguist and a lover of the classics, having in early life learnt Latin and Greek. He spoke French, German, Russian and Polish and was frequently engaged in the translation of technical works even up to within a week of his death. For many years he was an abstractor in the sugar section for the *Journal of the Society of Chemical Industry.*

In addition to his scientific work, de Whalley found time to interest himself in many other different spheres, and was for many years secretary and later president of the Cheerybles Musical Society. He was also a Freemason of long standing and high rank, Grand Lodge of England.

De Whalley married in 1883 Annie, only daughter of Z. Eastick, an early gas works chemist, and leaves a widow and twelve sons and daughters, nine of whom are married, and nineteen grandchildren.

We regret to announce the following deaths:

Prof. Michael Lenhossek, emeritus professor of anatomy in the University of Budapest, and president of the Hungarian Academy of Sciences, an authority on the histology of the nervous system, on January 26, aged seventy-three years.

Dr. F. Sowerby Macaulay, F.R.S., known for his mathematical work, on February 9, aged seventy-four years.

News and Views

Science and Social Ethics

THE attitude of scientific workers towards warfare, and what it now signifies to the future of the human race, has been the subject of many articles and other communications published in NATURE in recent years. Following a leading article in the issue of May 9, 1936, a letter from twenty-two graduate workers at the University of Cambridge was published in NATURE of May 16, and similar views on the international character of science and the barbarity of war were afterwards expressed by representatives of science in Cape Town and Bangalore. Whatever part physical conflict between individuals or communities has taken in the progressive development of man in the past, it cannot be questioned that the outlook for the future is very dark if all the resources of modern science are to be available for destructive purposes in the struggle for superiority among nations. Dr. Goebbels, who practically controls the Press of Germany, has said: "War is the most simple affirmation of life. Suppress war, and it would be like trying to suppress the processes of Nature". Such a primitive conception of the functions of war leaves out of consideration man's ethical and spiritual nature, and regards him purely as a fighting animal. Those of us who believe in a higher destiny for the human race cannot think it will be achieved through the use of high explosives, poison gas and incendiary bombs to settle disputes between civilized communities. It is because of such uses of their discoveries that scientific workers have not only the right but also the responsibility of making a collective pronouncement upon these disturbing aspects of our so-called civilization. Science has a message to deliver and a social mission to perform with far higher aims than those usually associated with it in the public mind. It believes in the evolution of social ethics, and therefore associates itself with all spiritual teaching which will promote peace upon earth and goodwill among men. On this account we are glad to put on record the following resolution adopted at the spring session of the Church Assembly at Westminster last week; and we suggest that a similar resolution might just as appropriately be passed at a representative assembly of workers for the advancement of natural knowledge.

The Christian Church and War

THAT this Assembly—

(1) endorses the Resolution of the Lambeth Conference, 1930, that war as a method of settling international disputes is incompatible with the teaching and example of our Lord Jesus Christ;

(2) deplores the general rearmament throughout the world;

(3) calls upon all Christian people to redouble their efforts to promote international good will;

(4) assures the Government of its moral support in all efforts to remove the political and economic causes of war, and in securing a general reduction of armaments by international agreement;

(5) welcomes the declared policy of the Government to adhere to the Covenant of the League of Nations, and to use armed force only for the defence of the country and in the interests of international security and peace;

(6) recognizes the right of the Government to maintain such forces as the Imperial Parliament deems necessary for the pursuance of this policy, and believes that, so long as this policy is maintained, Christian citizens may bear arms in the service of their country;

(7) affirms the responsibility of Christian people to support, criticize, or oppose all defence programmes in the light of Christian principles and in relation to their advancement of the Kingdom of God.

The University of Oxford Appeal

ON February 9, in speeches by Lord Halifax and others at the Goldsmiths' Hall in London, the appeal that the University of Oxford is making for money was launched. The capital sum aimed at is a million pounds, and some of the needs for which this sum is required are urgent. About a quarter of it is needed to ease the fund which the University has been accumulating for paying its share of the large cost of the extension to Bodley's library now being built. A similar amount is needed for the erection and equipment of new laboratories and other buildings. The remainder is required as a trust fund, the interest of which may be used to endow for a period of years new developments in any subject which looks promising, rather than be tied down to this particular subject or that. These needs are altogether separate from those of the medical school, which have been generously met by Lord Nuffield recently, and cannot be paid for out of his two million pounds gift. That gift, unlike some gifts, will not in any way be a liability on the University, but obviously the new school of clinical research which it is calling into existence, by quickening research throughout all departments of the University, must indirectly make new endowments of scientific departments a necessity. The needs for which the appeal is being made are, indeed, independent of, and of longer standing than, those of the medical school, and Lord Nuffield has recognized this by subscribing an additional £100,000 towards the million pounds required.

AGREEMENT has been reached as to the order in which the immediate scientific needs should be met. Most urgent is a new physics building for Prof. F. A. Lindemann. The Clarendon Laboratory of 1872, in which his department is housed, was never a suitable place for research, and despite the ingenious makeshifts its deficiencies have called forth, has now become almost intolerable. It is proposed to adapt this laboratory for the Department of Geology, at present cramped in the Museum itself, and to erect and equip a new building near the old and consequently near the other Physics Department, the Electrical Laboratory. The Clarendon should be a suitable place for the Department of Geology, which under the new professor to be elected soon should readily take on a new lease of life within it. Next, it is intended to build a physical-chemistry institute—the first *University* building for this subject—not, as might be thought most convenient, next to the Inorganic Laboratory (there is quite insufficient space available there for an adequate new building, especially when possible extensions of both departments are envisaged), but immediately on the other side of the Organic Chemistry Laboratory from it. Researchers in physical chemistry who now do their work in the laboratories and cellars of Balliol, Trinity and Jesus Colleges, overflowing at times into the engineering and organic chemistry laboratories, should find in the intended University institute an ampler and much more convenient home. After that building has gone up, it is hoped to rebuild, near by, the Physiology Laboratory, which dates from 1884.

Reflection of Radio Waves from the Middle Atmosphere

THE method of studying the ionized regions of the upper atmosphere by emitting small pulses of electric waves and recording the echoes reflected from the ionosphere is now well-known and is in everyday use in many parts of the world. The commonly recognized reflecting regions are at heights of 80 km. and above. Communications to the correspondence columns of NATURE of May 9 and 23, 1936, described observations indicating the existence of reflecting regions at much lower heights. These new regions were first discovered in May 1935, and an account of their investigation over a period of about a year from that date was given in a paper presented on February 4 to the Royal Society by R. A. Watson Watt, A. F. Wilkins and E. G. Bowen. A summary of the paper will be found on page 299. It appears from this work that there may be three electrified regions in the middle atmosphere at average heights of 10, 40 and 60 km., which are capable of reflecting radio waves of frequencies of the order of 6 megacycles per second and above (wave-lengths 50 metres and below). The lowest region has been found to be stratified to such an extent as to indicate the existence of five distinct layers at heights between 8·5 and 13·5 km., with reflection coefficients as high as 0·7. The observations so far made do not indicate any marked diurnal or seasonal changes. An interesting feature of the investigation so far conducted is that echoes from these layers have been recorded at sensibly vertical incidence at wave-lengths at and below those now in use for the television service. The existence of such echoes would cause the picture seen in a television receiver to have a doubled or blurred appearance. There is, however, insufficient evidence available to state how serious this possibility may be in the development of television services on the wave-lengths at present in use.

Auroral Display on February 3

REPORTS from various observers in Yorkshire and south Lancashire, who witnessed a display of the aurora borealis in the evening of February 3 last, have appeared in the *Yorkshire Post*. The aurora, which was evidently a striking phenomenon to those favoured with a clear sky, began about $18^h\ 30^m$ and lasted for an hour. One observer at Bradford noted a broad band of red passing overhead from east to west. On inquiry at the Royal Observatory, Greenwich, it was stated that a magnetic disturbance, which could be associated with this aurora, had been recorded at the Abinger magnetic station. The disturbance began suddenly on February 2 at $23^h\ 5^m$ U.T., and within a few hours a range of 220γ in horizontal force had been registered. The disturbance then died down, but was renewed between 17^h and 22^h on February 3; a typical movement (associated with auroras) in declination occurred about 19^h with a range of $\frac{3}{4}°$, the range in horizontal force being 190γ. At the commencement of the magnetic disturbance on Feb. $2^d\ 23^h$, the centre of the large sunspot, reported on p. 228 of NATURE of February 6, was about 40° west of the sun's central meridian and the following extremity of the spot about 32° west. A statistical analysis made at Greenwich of big sunspots and associated magnetic storms shows that spots of the size of the recent one are associated, in about two out of three cases, with either a large or a small magnetic storm, occurring on the average about $1\frac{1}{2}$ days after the central meridian passage of the spot. It may be added that 27 days (or a solar synodic rotation) before the aurora on February 3, the Abinger magnetic traces at about $19\frac{1}{4}^h$ on January 7 show a movement distinctive of auroral activity. An observer at the Saltburn Coastguard Station who saw the aurora on February 3 is reported by the *Yorkshire Post* as having stated that he "saw the lights a month ago".

The United States Floods

WHILST it is fully expected that the liability of the countryside to flooding through the possible bursting of the riverside levees in the Mississippi Valley will continue to be a menace for another week or ten days, yet there has been a perceptible diminution in the anxiety felt as regards the general situation, which is much more satisfactory than at the time of our previous issue. The crest of the flood wave is gradually diminishing in height. It did not quite reach the anticipated level at Cairo, and as it passes down the valley, unless reinforced by fresh rains, it should subside in intensity. There is believed to be a margin of at least four feet available above water surface level from New Madrid to New Orleans, and this should be adequate for the occasion. None the less, caution is being exercised, and some 120,000 workmen are being kept on the alert along the course of the river to deal at once with any incipient signs of weakness in the banks. In the Ohio Valley, the inhabitants are being permitted to return in detachments to their houses. The total death roll, as at present ascertained, amounts to 407, and the number of homeless is still in the neighbourhood of a million. At Louisville, several persons have been killed and a score or so injured in a series of explosions due to the ignition of an accumulation of gas in buildings following the inundation of the town.

As regards the damage done in the Ohio Valley, more accurate computation raises the figure to 527 million dollars (105½ million pounds) for the five States of Indiana, Kentucky, Illinois, West Virginia and Ohio. The fund contributed to the American Red Cross for the relief of sufferers has reached a total of three million pounds and the American Senate has passed a Bill authorizing a relief appropriation of 790 million dollars (158 million pounds). President Roosevelt has sent to Congress a report of the National Resources Committee with a message advocating the sanction of a "long-range plan and policy for construction" to ensure protection for the nation from a repetition of such calamitous experiences. The scheme is estimated to cost 2,750 million dollars (550 million pounds) and would occupy a period of about six years to complete. It covers flood protection and drainage work in almost every State of the Union.

Floods in France and Southern England

THE north of France has been experiencing an abnormal amount of rainfall during the past few days which has resulted in the flooding of extensive areas of country between Dunkirk and Cassel and between Hazebrouck and Armentières on the Flanders frontier. The River Lys has overflown its bank both at Armentières and Bethune, while at Houthnes a number of dwellings have had to be evacuated. The bursting of a dam at St. Denis, north of Paris, has resulted in local flooding to a depth of five feet, and some fifty families have had to leave their homes. In southern England, after some further heavy rainfall and a resumption of the rise in the level of the Thames, the flood waters are again subsiding, and there does not seem to be further cause for alarm.

A Volcano under an Ice-Sheet

AT an evening meeting of the Royal Geographical Society on February 8, Dr. Niels Nielsen gave an account of volcanic eruptions in 1934 and 1936 underneath the ice-cap of Vatnajokull in Iceland. Subglacial volcanic outbursts of this character have been known for many years from the catastrophic floods—known in Icelandic as *Jökullhlaup*—which result from the melting of the ice adjacent to the hot lavas and ashes, but until the investigations of Dr. Nielsen and his collaborators, no scientific accounts of these phenomena were available. It appears likely that there are at least two types of these volcanic outbursts—one, as at Grímsvotn, probably of central type, with a relatively small output of ash material but enormously energetic, forming craters in the ice; and another at Hágongur, perhaps a fissure eruption, which produced a considerable amount of lava but so little energy that it was unable to penetrate through an ice-sheet only 100–200 metres thick. The volume of glacial melt-water liberated by the first of these volcanic outbursts was in the neighbourhood of ten thousand million cubic metres. The geological interest of these remarkable phenomena is great. Following upon the University of Glasgow geological expedition to Iceland in 1924, Dr. Martin Peacock postulated that the early-glacial 'palagonite formation', a great series of globular basalts and tuffs which covers very extensive areas in Iceland and builds up some of the highest mountains in that island, was formed by the extrusion of lavas under the thick Pleistocene ice-sheet. Dr. Nielsen (*Geografisk Tidsskrift*, Dec. 1936) has shown that rocks wholly similar to the palagonite formation have been formed in these recent eruptions, with the result that Peacock's hypothesis is now brought within the realms of established fact.

Transition State in Chemical Reaction

THE thirty-sixth Bedson Lecture was delivered by Prof. M. Polanyi, of the University of Manchester, on February 1, in Armstrong College, Newcastle-on-Tyne. Prof. Polanyi took as his subject, "The Transition State in Chemical Reactions", and illustrated his remarks with particular reference to the ozone-oxygen reaction. Molecules are closely-packed groups linked by chemical bonds and separated by wider gaps from other molecules. The course of a chemical reaction between the molecules involves the breaking of these original chemical bonds, with the formation of new ones. During this change, the gaps between the initial molecules disappear and new ones appear between the final molecules, and between these two states there must be an infinite number of atomic configurations. At some point between the initial and final gaps separating the molecules, there is an intermediate state when no distinction can be drawn between the initial and final states. This is defined as the 'transition state of the reaction'. Turning from the purely geometric to the energy conception of the transition state, Prof. Polanyi demonstrated how the potential energy in the reaction between the molecules rises to a maximum. The position of the maximum indicates the transition state, and further, the energy of the reaction must be sufficient to surmount this energy barrier. Hence the plotting of the energy changes occurring in the reaction of two particles will indicate the transition state and the energy of activation of the reaction. Prof. Polanyi traced the evaluation of the energy changes and showed how it was possible to determine the heat of activation by application of wave mechanics and molecular constants. He also indicated how various properties of the transition state determine the changes in reaction rate caused by varying conditions such as hydrostatic pressure, change of solvent, etc.

Scientific Associations of Coventry

A JOINT meeting of the Coventry Engineering Society and the Midland Branch of the Institute of Physics was held in the Coventry Technical College on February 5, when Sir James Jeans delivered a lecture on "Some Large Scale Problems of Astronomy". Sir Alfred Herbert, president of the Society, presided over an audience of more than 900. Prior to the meeting, a civic reception was given to Sir James Jeans, and in welcoming him and Lady Jeans to Coventry, the Mayor (Alderman A. H. Barnacle) mentioned some well-known men of science who had been associated with Coventry. Among them were Thomas Huxley, who spent his boyhood in the City, and Sir Norman Lockyer, who was born at Rugby and spent his youth at Ashow, and was connected by marriage with some of the oldest families in Coventry. In speaking of Sir Norman's work, the Mayor pointed out that he founded NATURE, which he referred to as the leading scientific periodical of its kind in the world. In his reply, Sir James recalled an early visit to Coventry when he was about five years of age; he was shown a tree which he was told marked the centre of England, but, he continued, "I wondered how a tree could be the centre of an area which I imagined was nothing like circular". Following the reception, a private dinner in honour of Sir James and Lady Jeans was given in the ancient St. Mary's Hall by Sir Alfred Herbert. Among those present were representatives of the Institute of Physics and well-known local industrialists and civic officials.

Centenary of Practical Marine Screw Propulsion

To mark the centenary of practical marine screw propulsion, a special exhibit was opened at the Science Museum, South Kensington, on February 11. In accordance with the usual practice of the Museum, this shows both the history of the pioneer experimental work, as well as the subsequent developments and current practice in marine screw propellers. In February 1837, Francis Pettit Smith successfully tried his first screw-propelled steam launch (a model of which is shown) on the Paddington Canal. The screw had two complete turns; on one of the trips it struck an obstacle, and about one-half of it was broken off. To the inventor's astonishment, this accident materially increased the speed of the boat. The S.S. *Archimedes* (1838) was fitted with a double-threaded screw of half a turn, in accordance with Smith's amended patent. Other historical exhibits include models of Ericsson's experimental screw of 1837, and those of the S.S. *James Lowe* (1838), the S.S. *Novelty* (1839–40), and the first French screw steamer *Napoléon* (1843). Screws were at first used as an auxiliary means of propulsion, and in order that they should not impede the vessel when under sail only, lifting screws (an example by Maudslay, 1846, is shown) were introduced, which could be disconnected from the shaft and raised clear of the water. Other developments represented are the 'common screw', which was the most successful form of propeller up to about 1860, Hirsch's propeller (1860–66), and the adjustable pitch propeller patented by Griffiths in 1868. Various examples of modern practice are also included, notably a model of the four-bladed bronze propellers of the Cunard White Star liner R.M.S *Queen Mary*, which are 20 ft. in diameter, each weighing 35 tons. These are the largest screw propellers which have ever been cast in one piece.

Gift to the Massachusetts Institution of Technology

IN connexion with the announcement last month of a bequest of one million dollars to the Massachusetts Institute of Technology under the will of Mr. Charles Hayden, Dr. Karl T. Compton, president of the Institute, has issued a statement in the course of which he says that: "Mr. Hayden's generous bequest to the Massachusetts Institute of Technology only serves to emphasize the constructive value of his life-long interest in the institution and the great personal loss suffered in his passing. At the time of his death, he was not only a member of the corporation of the Institute but was also a member of its finance committee, chairman of its student loan fund committee and chairman of the research associates of M.I.T. To the latter two of these activities Mr. Hayden had been a generous contributor as well as active in their administration. Mr. Hayden's interest . . . in his professional training in mining engineering was given material expression in his contribution of a principal portion of the funds used in the construction of the Institute's building devoted to mining and metallurgy. In addition to these major contributions Mr. Hayden was continually and quietly contributing to student needs. . . . His specific bequest of one million dollars to the Institute gives us great encouragement and will enable us quickly to make substantial progress in the twelve and a half million dollar program of objectives which were approved by the corporation last October as representing the urgent needs of the institution at this time"

Lawrence Memorial Medal

THE Lawrence Memorial Medal of the Royal Central Asian Society has been awarded to Sir Charles Bell, the great authority on things Tibetan, whose friendship with the late Dalai Lama was an outstanding event in British relations with Tibet, and who has an intimate and authoritative knowledge of events in Tibet and Mongolia, on which he has written valuable books. This is the second award of this medal, the first having been made to Major J. B. Glubb, in recognition of his work in administering the nomad territory of Northern Arabia, which lies within the frontiers of Trans-Jordania, and the success he has had in promoting friendly relations between the tribes of that region. The Lawrence Memorial Medal was founded by the Society in memory of T. E. Lawrence, under the then president, the late Lord Allenby. It exists to recognize work of outstanding distinction in travel, research or letters, when such work contributes to the study and the solution of the problems of Asia, made by officials, travellers, students or others who are working in the area covered by the activities of the Royal Central Asian Society.

London Television Service

THE first public demonstrations of the reception of television programmes from the British Broadcasting Corporation's experimental station at Alexandra Palace were given on the occasion of the Radio Exhibition at Olympia in August 1936. These were followed in November by the inauguration of the present television broadcasting service from the same station. In accordance with the recommendations of H.M. Postmaster-General's Television Advisory Committee, the programmes were shared between two separate transmitters installed respectively by the Baird Television Co., Ltd., and by the Marconi–E.M.I. Television Co., Ltd. The object of this arrangement was to enable an adequate, practical test to be made to ascertain the relative merits of the two systems of transmission, which differ considerably in technical details and in scanning speed and picture frequency. According to an announcement in *The Times*, the Television Advisory Committee has now recommended that the experimental period should be terminated, and that a single set of technical standards should be adopted for public transmissions from the London station. This recommendation has been approved by the Postmaster-General, and provides for a standard of interlaced scanning at a speed of 405 lines per picture, with a picture frequency of 50 per second. The result of this decision is that in future the B.B.C. television programmes from the Alexandra Palace will be emitted by the Marconi–E.M.I. system, although it may be possible to convert the Baird system to the required standards at a later date. The adoption of the new standards, which will not be altered before the end of 1938, will render possible a certain degree of simplification in the design of television receivers. In common with those of other firms, the existing receiving sets made by the Baird Company are capable of receiving the Marconi–E.M.I. transmissions.

Sir Joseph Banks's London House

IT is too late to protest against the destruction of Sir Joseph Banks's town house at 32 Soho Square, and our commercial age will demand its removal together with many other examples of eighteenth century domestic architecture. Only the tablet placed on the house in 1911 and the description and plan in *Country Life* of September 27, 1913, will remain to us. Sir Joseph moved there from New Burlington Street in the autumn of 1777, and remained there until his death in 1820. The Linnean Society leased part of the house from 1827 until 1857, when it moved to Old Burlington House. The subsequent tenants, including the Hospital for Diseases of the Heart and a firm of decorators, made many alterations, but the fine ceilings and an exquisite overmantel and fireplace were reminders of its original beauty. Banks's magnificent collections were housed there under the able care of the botanist-librarians Solander, Dryander and Robert Brown. Banks bequeathed his collections to Brown, who transferred them to the British Museum, remaining in charge of them until his death in 1858.

A National Industrial Health Service

THE Medical Research Council, with the Industrial Health Research Board as well as the various colleges and schools of the universities, are occupied with research work which has, either directly or potentially, an industrial application; the time-lag, however, in applying or testing the results of such research work is usually too long. Some large organizations provide a full-time medical service, but there are many which have not yet realized that there is any need for such a service, and the smaller organizations cannot afford this. Even when a medical officer is appointed, his previous education has not trained him to recognize, or to deal adequately with a number of problems he meets, nor does he know where to get the required knowledge which, unknown to him, may exist. With the rapid development of new processes utilizing new products, it is necessary that their physiological and toxicological properties should be studied: also the medical officer will find himself confronted by a number of psychological problems concerning which he knows little or nothing. Discussions of the problem of making practically effective in industry the results of research work of medical importance have appeared in *Industrial Welfare* of December 15 and the *British Medical Journal* of December 5. Since it seems impracticable to add anything to the curriculum of the medical student, a post-graduate course is suggested. The works' doctor must be able to ascertain that (*a*) the workers taken on for certain jobs are reasonably fit to carry them out from the health point of view, and (*b*), in co-operation with works' engineers and others, that the conditions under which the employees are required to work are not prejudicial to their health.

SINCE small organizations cannot afford to give the medical services possible to the larger ones, some way of providing them must be considered. One way would be for a number of small organizations to be served by one medical officer; there are, of course, difficulties in the way, but they need not be insuperable. Who shall pay for these services must also be considered. Shall the organizations or the State? It is suggested that a National Industrial Health Service should be formed, which should include not only a medically qualified personnel, but also a number of engineers who have been trained in the study of works' practice from the physiological point of view, physiologists and medical-industrial psychologists. Not only would the curative aspect of industrial medical practice be dealt with but also the preventive, and this would involve the study of the conditions of work and the total environment of the employees. It would also be the business of this service to keep in touch with existent research work and bring it to the notice of those concerned. There should also be some arrangement whereby the application of a particular piece of research or investigation could be considered: for this a special committee or board is needed, comprising representatives of the State, the industry concerned, the trade union or unions representing the particular industry, and the research worker or organization responsible.

Supply of Vitamins in Soviet Russia

PROF. P. V. GOLOVIN, president of the Vitamins Council of the Soviet Commissariat of the Food Industry, has recently stated that whereas the anti-scurvy vitamin C used previously to be manufactured from conifers, it is now being made from the sweet briar rose. Vitamin C is mainly used by people living in the north and in the Arctic. In 1935 three million doses of this vitamin were manufactured in Soviet Russia, and in 1936 thirteen million doses would be turned out. Confectionery factories are now producing caramels, sugar plums and jellied sweets containing vitamin C. Two vitamin factories have been constructed in Leningrad and Schnelkovo. In the latter place a vitamin combine is being built which would produce vitamin A in addition to vitamin C. In Moscow a factory has been built for the manufacture of anti-rickets vitamin D obtained from yeast.

Announcements

SIR ALBERT SEWARD, formerly professor of botany in the University of Cambridge, was elected an honorary member of the New York Academy of Sciences at its annual meeting held on December 21.

LORD SWINTON, Secretary of State for Air, has appointed Dr. D. R. Pye to be director of scientific research in the Department of the Air Member for Research and Development, Air Ministry, on the retirement of Mr. H. E. Wimperis, and Mr. W. S. Farren to be deputy director of scientific research in succession to Dr. Pye

DR. E. NEAVERSON has been awarded the Medal of the Liverpool Geological Society. Dr. Neaverson, who is senior lecturer (palæontology) in the Department of Geology of the University of Liverpool, is well known for his work on the Carboniferous rocks of North Wales and the Quaternary beds of the Rhyl district. Farther afield, he has carried out research on the bottom-deposits collected on the voyages of the R.R.S. *Discovery*. He is a past president of the Liverpool Geological Society.

THE following appointments have recently been made to the Colonial Service: A. C. E. Callan, produce inspector, Agricultural Department, Zanzibar; W. K. Hubble, principal, Kadoorie Arab Agricultural School, Tulkarm, Palestine; G. F. Clay, (deputy director of agriculture, Uganda), assistant director of agriculture, Nigeria; W. F. Jepson, (Phytalus investigator), entomologist, Agricultural Department, Mauritius; H. Macluskie (agricultural superintendent, British Guiana), agricultural officer, Sierra Leone.

IT is announced in *Science* that, following the Harvard tercentenary, the French Government has conferred membership in the Legion of Honour with the rank of commander on President J. B. Conant. Prof. George D. Birkhoff, Prof. Julian L. Coolidge, Prof. James B. Munn and Jerome D. Green, director of the tercentenary, have been promoted from the rank of chevalier to that of officer of the legion. The rank of chevalier has been conferred on Profs. Bliss Perry, Edward B. Hill, Edward W. Forbes, Roger Bigelow Merriman, Ralph Barton Perry, Edward A. Whitney, Kenneth J. Conant and George H. Edgell.

THE one hundredth and fifth annual meeting of the British Medical Association will be held in Belfast, commencing on July 16. The president-elect is Prof. R. J. Johnstone, professor of gynæcology in Queen's University, Belfast.

THE Faraday Society will hold a general discussion on "The Properties and Functions of Membranes, Natural and Artificial", on April 22–24, at University College, Gower Street, London, W.C.1. Another discussion on "Reaction Kinetics" will be held in the University of Manchester on September 13–15. As is usual at these general discussions, contributions will be made by a number of foreign men of science. Further information can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, W.C.1.

A SERIES of eight lectures on "The Economic Problem and World Peace" to be given in the Essex Hall, Strand, London, W.C.1, during February and March has been arranged by the National Peace Council. The first lecture, on February 8, was given by Graham Hutton on "The Continental Western Democracies". Subsequent lectures cover "The Small Countries of Central and South-Eastern Europe" (T. Balogh); Germany (B. Thomas); Italy (H. Fines); the Soviet Union (L. Segal); Japan and China (F. Utley); the United States (H. Quigley) and the British Empire (H. V. Hodson). The lectures are to be given on Mondays at 6.15 and tickets (4*s*. for the course) and other particulars can be obtained from Mr. G. Bailey, National Peace Council, 39 Victoria Street, S.W.1.

THE Rockefeller Foundation has recently given 9,000 Swiss francs to the University Psychiatric Clinic at Bern for the erection of a laboratory for investigation of the anatomy of the brain.

NORWAY has introduced a regulation by which no professional motor-driver may consume any alcoholic beverage while driving or during the previous eight hours. In suspected cases a blood test is carried out, when, if the blood has an alcohol content of more than 0·5 per mille, the law will be considered to have been broken.

IN the letter entitled "Equivalent Particle Observers" by Prof. Leigh Page in NATURE of January 16, p. 111, the first sentence of the second paragraph should read: "My approach to the relativistic kinematics differs from Milne's in that I employ the concept of equivalence to establish reference systems consisting of dense aggregates of synchronous particle-observers relatively at rest".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 290.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Nature of the Causative Agent of the Rous Fowl Sarcoma

THE opinions of workers in the field of Rous sarcoma are divided into two schools, one of which uses as a working hypothesis the suggestion of Fraenkel[1] that the agent is a pure chemical substance or a 'virus-enzyme', while the other considers it to be a particle resembling a virus. These opinions are represented by two quotations from recent publications. Murphy[2] states that "Without proof that normal tissues harbour the cancer virus, a fantastic conception and one difficult of experimental test, the virus theory for the etiology of cancer appears untenable. The only proved relationship is that a virus may act as a carcinogenic agent in initiating changes leading to malignancy, but has no part in the formal genesis of neoplasms." Against this may be set the contention of Amies[3] that "The total evidence seems, therefore, sufficiently strong to justify the conclusion that the tumour agents exist in the form of elementary bodies similar to but somewhat smaller than those which represent the causal agents of such typical virus diseases as Vaccinia and Fowl-Pox".

We have confirmed the fact that it is possible to deposit the agent from extracts of Rous sarcoma by centrifugation at 15,000 r.p.m., but we have been unable to obtain satisfactory correlation between the number of elementary bodies in different active preparations and the infectivity of the extracts. The supernatant after centrifugation is usually much less active and contains many fewer ultra-microscopic particles than the original extracts, but the infectivity of material concentrated many times on the centrifuge is seldom so active as would be suggested by the enormous numbers of elementary bodies present. An example will make this point clear :

Material injected	Minimum volume required to give tumour	Ultra-microscopic appearance
Original Extract	0·005 c.c.	Very large number of particles
Supernatant after centrifuging for 1 hour at 15,000 r.p.m.	0·50 c.c	Very few particles
Deposit made up in 1/45 of original volume	0·20 c c.	Very large number of particles

This observation was confirmed by the use of eluates prepared from the deposit obtained by adsorption of tumour extracts on to Willstatter's alumina[5]. In such eluates we have often observed very few elementary bodies, and yet they had an activity comparable with that of the original extract. Our impression is that the tumour-producing activity of Rous extracts is associated with material which can be deposited at 15,000 r.p.m., but we believe that only a small proportion of the elementary bodies visible in the extract can be associated with that activity, and we would emphasize that the possibility that the active agent is adsorbed on the surface of such particles cannot be excluded. Particles with similar optical properties can be obtained from normal tissues or glycogen solution by fractional centrifugation. Such a process in itself ensures uniformity of optical properties in the product, so that if all the particles in a preparation are similar in appearance, this gives little information as to uniformity in their chemical or biological properties.

The hypothesis of a purely chemical agent of the Rous sarcoma seemed to be confirmed when Jobling and Sproul[6] claimed that repeated injections of an acetone extract of fresh Rous sarcoma tissue would produce similar tumours. They stated further that if the residue from extraction was extracted again with acetone, the extract would only produce tumours if incubated with an extract of 'normal' tissue obtained by the injection of kieselguhr into the breast muscle of normal fowls. Tumours could also be obtained with carbon tetrachloride extracts of dried sarcoma powder if treated in the same way with 'normal' tissue extract.

We have attempted to repeat this work using acetone extracts of fresh tumour and dried sarcoma powder. We have kept our material as free from oxygen as possible throughout the experiment, and acetone extracts have always been thoroughly centrifuged at 3,500 r.p.m. and filtered through paper before removal of the solvent. Material was prepared for injection by dissolving in a little acetone and pouring into Ringer solution. Fine suspensions obtained in this way were injected alone or after incubation with 'normal' tissue extract, as described by Jobling and Sproul. We have also incubated the inoculum with embryo extract and with residues left after extraction, but we have never obtained a tumour by any of these means. We have, however, obtained tumours by injection of the residue left after acetone extraction of dried sarcoma powder, in agreement with the observation of Claude[7], but no activity has been observed in the residue left from acetone extraction of fresh sarcoma tissue.

Unless our technique has differed in some way we have not appreciated from that of Jobling and Sproul, we must conclude that their results were due to fine suspensions of active material in their solvents, and this possibility is enhanced by the fact that in our experiments with dried powders the activity remained in the residue after extraction. This conclusion is disappointing from the point of view of the 'chemical' hypothesis, but it does not exclude the conception suggested by the phrase 'virus-enzyme', as such a substance might be expected to be insoluble in acetone.

Measurements of Oxide Films on Copper and Iron

RECENT letters from Dobinski[1] and Nelson[2] report the rapid appearance of oxide upon unheated copper and iron on exposure to air. This oxide, which doubtless causes the rapid change in the behaviour of these metals to silver and copper nitrates respectively[3], can be estimated by measuring the number of millicoulombs needed for its cathodic reduction. The principle was formerly used to measure silver iodide films[4], and gave numbers agreeing with both gravimetric and iodometric methods. For oxide films it has yielded results in reasonable accord with optical[5] and gravimetric methods (see accompanying table), and consistent with early chemical determinations made on the films after stripping[6]. Former disagreement between gravimetric and optical methods has been largely due to neglect of invisible films, or to different meanings attached to the term 'thickness' as applied to a non-uniform film on an uneven surface.

THICKNESS (MEAN GENERAL INTERCEPTS*) OF OXIDE-FILMS.

Iron tinted to:	Electrical (New)	Optical (Constable)	Gravimetric† (New)
Straw	440A.	460A.	390A.
Reddish yellow	530	520	470
Red brown	560	580	500
Purple	625	630	560
Violet	695	680	625
Blue	725	720	650

Copper tinted to:	Electrical (New)	Optical (Constable)
1st Order		
Dark brown	370	380
Red brown	410	420
Purple	460	450
Violet	485	480
Blue	520	500
Silvery green	800	880
2nd order		
Yellow	940	980
Orange	1,170	1,200
Red	1,240	1,260

* We believe that both electrical and optical methods give the mean of the intercepts made by normals to the *general* plane of the surface. Some authorities prefer to use the word 'thickness' as denoting the mean intercept made by the *local* normals; if so, it is necessary to divide by the specific surface.

† The invisible oxide present on the surface during the first weighing must be determined electrically; the effect of *embedded* oxide will be considered in the Carnegie Scholarship Memoirs, vol. 25.

Having thus been tested on films of the interference colour range, the method has been applied to measure the invisible oxide produced on copper in a desiccator at 18° or in a furnace at 62° C. The points on Fig. 1 (each the mean of at least four determinations) may all be affected by a constant 'zero-error', due to eutectic oxide or other causes; this will not influence the shapes of the curves.

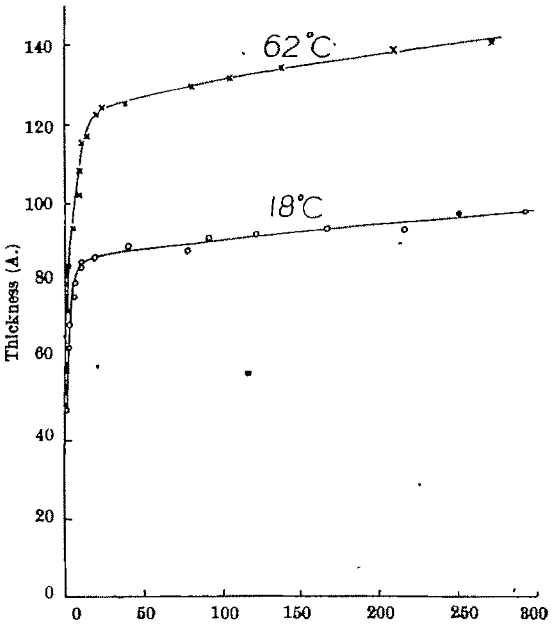

Fig. 1.

Additional results on iron will appear later in the Carnegie Scholarship Memoirs, vol. 25.

Exchange Reactions of Iodine Compounds

JULIUSBURGER, Topley and Weiss[1] found by the artificial radioactive indicator method that an exchange takes place between sodium iodide (*c.* $0{\cdot}5M$) and methyl iodide (*c.* $2M$) in alcoholic solution at room temperature; the exchange is complete in a minute or two. Under similar conditions, allyl iodide exchanges with sodium iodide, but ethyl, propyl, isopropyl and methylene iodides do not; nor does iodoform exchange in acetone solution. Further, Gluckauf and Fay's[2] successful concentration of active iodine from methyl iodide after neutron bombardment shows that no appreciable exchange occurs between iodine and methyl iodide in the absence of a solvent.

I have confirmed and extended these results (with the exception of the allyl iodide exchange). The technique for alcohol and acetone solutions was essentially the same as that of Juliusburger, Topley and Weiss, namely, a separation of the organic iodide by adding water; the activities of these compounds were, however, measured directly on the Geiger-Muller counter, which was adapted to measure liquids as well as solids.

In the experiments involving free iodine the separation was effected by shaking with mercury and decanting off from the mercury iodides formed.

The methyl iodide-sodium iodide exchange was carried out in both directions, that is, first starting with active sodium iodide and then starting with active methyl iodide (prepared by exchange with active sodium iodide). (There is no reason to suppose that the other reactions mentioned here could not also be carried out in both directions.) This was done both in alcohol and acetone solution—the latter to give a better comparison with the iodoform experiment—and the exchange starting with active sodium iodide was also done in amyl alcohol solution. The exchange was, moreover, successfully carried out in alcohol in the presence of sulphur dioxide, which shows that it is not dependent on the presence of traces of free iodine.

The methyl iodide-iodine exchange was also tested in the reverse direction, using active methyl iodide prepared as described above and separating the iodine by passing in sulphur dioxide and thus obtaining it in the form of an aqueous iodide solution, from which silver iodide was precipitated; no exchange was found. No exchange was found in carbon tetrachloride, carbon disulphide, or ether solution.

Although methyl iodide is the only alkyl iodide which exchanges with sodium iodide in dissociating solvents at room temperature, an exchange was established for ethyl, propyl, isopropyl, butyl and isoamyl iodides at 100° C.; the experiments were done in sealed tubes. The reaction was approximately complete after 15 minutes in all cases. In the case of ethyl iodide it was shown that the exchange is nearly complete after 15 minutes at 50°–55° C. Methylene iodide and iodoform also exchange with sodium iodide at 100° C. in alcoholic solution. The addition of a few drops of concentrated hydrochloric acid failed to make ethyl iodide or iodoform exchange at room temperature.

Some aromatic compounds, namely, phenyl iodide, *p*-nitroiodobenzene, and *p*-iodoaniline, were tested under similar conditions at 100° C. but failed to exchange.

Iodoacetic acid exchanges with sodium iodide in aqueous solution at room temperature, but β-iodopropionic acid does not. The acids were separated by adding sodium sulphate and extracting with ether. *m*- and *p*-Iodobenzoic acids also failed to exchange with sodium iodide in acetone solution (separation by adding water).

Further experiments, including kinetic measurements, are in hand.

I wish to express my thanks to Prof. G. Hevesy for his very valuable advice and suggestions.

Note added in proof.—The methyl iodide - iodine exchange takes place in 15 minutes at 100° C., but not in 2–3 minutes at room temperature in alcoholic solution; at 100° C. the reaction was tested in both directions. No reaction was observed at 100° C. in the absence of a solvent, starting with active methyl iodide. (Separation, starting with active sodium iodide, by adding water and passing in sulphur dioxide; starting with active methyl iodide, by shaking well with sodium iodide solution—with which the iodine exchanged—washing the iodide solution with chloroform, and precipitating silver iodide.) It may be concluded that iodine ions are necessary for the exchange.

β-Iodopropionic acid and sodium iodide exchange nearly completely in aqueous solution on warming to the boiling point for a minute or two.

A Relation between the Lyotropic Series and Free Energies

Many physical-chemical properties and reactions of solutions, such as hydration of ions, flocculation of sols, swelling and liquefaction of gels and surface tensions, are influenced by the presence of ions the order of effectiveness of which is often expressed as the lyotropic or Hofmeister series. The order is not invariable and, whilst factors such as hydrogen ion concentration, valency and activity are of much importance[1], the series appears still to embody some fundamental property. It is of much interest, therefore, that the order of the anions arranged in the lyotropic series runs closely parallel with the order of the (Gibbsian) standard free energies of formation from their elements (see accompanying table).

STANDARD FREE ENERGIES OF ANIONS RELATIVE TO $\Delta F^\circ_{H^+} = 0$.

Anions Conventional Lyotropic Series	Others	$\Delta F^\circ_{298 \cdot 1}$ kgm. cal./gm.-ion
Tartrate		?
Citrate		?
SO_4''		− 176·5
	Oxalate	− 158
	Fumarate	− 144·6
	HSO_3'	− 123·9
	SO_3''	− 116·7
Acetate		− 89·7
F'		− 65·7
	IO_3''	− 31·6
Cl'		− 31·3
NO_3'		− 26·5
Br'		− 24·6
	CNO'	− 23·8
I'		− 12·3
	ClO_4'	− 10·9
	NO_2'	− 8·5
	ClO_3'	− 0·3
SCN'		?
	BrO_3'	+ 2·3
	HS'	+ 2·9
	CN'	+ 39·4

The halides are spaced as one would expect, and the bromide-nitrate pair, which have similar lyotropic properties, have also similar free energies. The second column includes ions less often investigated, and shows the position forecast for them if the general thesis is true. Except for the chlorate ion, this order agrees with such scattered records as have been found. Furthermore, when the free energy of formation of the thiocyanate ion becomes known, one would expect it to be around zero or positive.

Although a fundamental relationship between the lyotropic series and some change or other in free energy might well be anticipated, it is not obvious (except perhaps for the halides) why the free energy of formation of ions from their constituent elements should show such a close apparent relationship, since complete disintegration of oxy-acids is not in question. The free energies of formation of the halide ions are proportional to their standard electrode potentials, so that for these an explanation of the lyotropic series may perhaps be sought in their relative readiness to engage in electron transfer.

It is suggested, therefore, that a more quantitative study of the series from the thermodynamic and electrode potential points of view at equal concentrations of hydrogen ions may well lead to results of great interest.

A Photochemical Antagonism of Radiations

THE chemical action of light of different wavelengths on a thermal oxidation-reduction equilibrium of the following type:

$$A + BH_2 \rightleftarrows AH_2 + B$$

may, under certain conditions, in the absence of oxygen, lead to displacements in opposite directions. Suppose that the hydrogen acceptors A and B have each an absorption band in different parts of the visible spectral region, A absorbing mainly the longer waves ($\lambda \sim 700$–500 mμ) and B the shorter ones ($\lambda \sim 500$–400 mμ). Then light of longer waves may drive the equilibrium to the right and that of the shorter waves to the left. A good example of such an equilibrium in a liquid system is constituted of the two oxidation reduction systems: methylene blue (A)—leucomethylene blue (AH_2) and phenylhydrazine-sulphonate (BH_2)—benzenediazosulphonate (B) in diluted acid solutions[1].

The following qualitative experiment shows the light-effects very well. A dark-equilibrium mixture of the reaction components in 0·01 molar hydrochloric acid, the concentrations of B and BH_2 being about 0·01 molar and that of methylene blue about 0·0001 molar, is divided between two test tubes. The first tube stands in a tartrazine solution absorbing the radiation of shorter wave-lengths (blue, violet and near ultra-violet); the second in a saturated copper sulphate solution, chiefly absorbing in the red and yellow spectral region. Exposure to sunlight will give a more or less rapid bleaching of the dyestuff in the first tube, but an increased concentration of dyestuff in the second. A stationary state is reached, regulated by the light intensity and the thermal reactions, the velocity of which is increased with the temperature to about double for an increase of about ten degrees. The thermal reaction: $A + BH_2 \rightarrow AH_2 + B$ also shows a very prominent dependence on the hydrogen ion concentration, increasing rapidly with the latter. On the reverse reaction, $B + AH_2 \rightarrow BH_2 + A$, the acidity has no such marked influence. After the cessation of illumination, the original equilibrium is restored by the thermal reactions.

On the other hand, the photo-active absorption of the two hydrogen donators, AH_2 and BH_2, are situated in the near ultra-violet (AH_2) and in the middle ultra-violet (BH_2). The spectra are characterized by a marked predissociation: both components are dissociated adiabatically by the absorbed radiation into an activated acceptor-molecule and gaseous hydrogen. In the presence of a suitable catalyst absorbing hydrogen, such as platinum black, the reverse recombination process goes on after completed illumination. The energies of dissociation may be preliminarily discussed on the basis of Franck's postulate from the equivalent energies of radiation on the absorption thresholds or maxima, and the calculated values are in an approximate agreement with the results obtained from electrometrical measurements (about 30 kcal./mol.).

According to J. Weiss[2], the quenching of dyestuff fluorescence by ferrous ions and SH-compounds is connected with photo-reactions in which the light quantum is transferred from the excited dyestuff molecule to the quenching component (hydrogen donator) by a collision of the second kind. Thus the dyestuff, activated by the visible radiation, replaces a light quantum of higher frequency, splitting the hydrogen donator directly. The same mechanism may be valid here.

A complete investigation of the photo-reactions is going on, and will be published elsewhere.

Gradients in Wool Growth

THE purpose of this letter is to suggest a possible fundamental and common interpretation of results derived by various investigators, including myself, from fleece analyses and from experiments concerned with the effects of diet and abnormal conditions on fleece and fibre characteristics. A recent paper by Swart[1] is one account of this kind of experimentation. Work of a different kind and concerning fibre-type arrays is described in a stimulating paper by Dr. Galpin[2]: it appears to be possible to link together results from such apparently different types of work.

Dr. Galpin states that in the New Zealand Romney lamb there is a main gradient in fibre-type arrays from britch to poll. Recent investigations of my own[3,4] point to a main gradient of a similar kind in mean fibre fineness: one fleece, for example, exhibited mean diameter at the shoulder region of 31·4μ and this gradually increased to 33·3μ at the britch.

Generally the finer parts of the fleece occur anterodorsally. Admitting general embryological evidence and results of studies on the fœtal development of the sheep[5], one must, I think, accept the idea of a physiological skin activity greater in the forward parts of the body than it is in the britch region. Assuming this, there is thus the apparent contradiction that where the activity is *greater*, the fibres are generally *finer*. This may be explained in the following way. The greater activity anteriorly is not expressed by the production of coarser fibres, but often by *a greater number of fibres*, that is, a fleece density which is greater anteriorly than posteriorly. General evidence for this view is supplied by analysis from three different breeds. In Suffolk, Cheviot, and Welsh Mountain fleeces examined, there appears to be a main antero-posterior gradient in number of fibres per unit area. In a Welsh Mountain fleece, density decreased from 7,960 fibres per 4 sq. cm., at the shoulder, to 6,770 in the britch region. Additional evidence is furnished by a study of coat development in the fœtus. In all stages the follicles are very much greater in number over the neck and shoulder than elsewhere, diminishing in number more posteriorly and ventrally. There is here a definite gradient in number of follicles. Incidentally, although high density may later cause the production of fine fibres, it is difficult to appreciate Dr. Galpin's point of view that even some differences between arrays are the results of 'overcrowding' at such an early stage as the trio-stage.

It has been stated that there are no gradients in fibre fineness, because relatively large variations occur over small areas of the fleece, and what has been named 'spotted' or short-period variation is evident. I think this is a narrow view. Main trends do occur over the fleece, certainly more evident in the less uniform fleeces, and about these trends occurs the short-period variation. Often the practical necessity of taking relatively few samples for measurement has served only to demonstrate the short-period variation, which has masked any possible indications of gradients which exist. In very uniform fleeces gradients are more difficult to demonstrate, but they are manifest in other types and in the coats of lambs.

Another possible expression of greater activity forward is in the greater length of fibre. Swart states that a ration increased from sub-normal caused increased fibre-length, and the effect was more marked on the back than on the britch and belly. Results of a few analyses I have made, especially on the Welsh Mountain fleece, tend to indicate that there is a main antero-posterior gradient in straight-length of fibre, one fleece, for example, having mean values between 13·6 cm. at shoulder and 12·4 cm. in the britch region.

Many investigations are required to demonstrate subsidiary gradients and to substantiate or disprove these possible explanations. Such suggestions as those I have made are only tentative and arise from a desire to apply a coherent and unifying significance to the mass of results being published.

Effect of Vitamin E Deficiency on the Thyroid

SINGER[1] found that vitamin E deficiency produced hypoplasia of the thyroid in rats. I have noticed what appears to be cretinism in the young of vitamin E-deficient rats. Female rats kept on an E-free diet usually have an initial fertility and produce a litter of living young before becoming absolutely sterile; the litters of such rats or of rats which have been proved sterile and have then been given a small dose of vitamin E concentrate, just sufficient to produce a litter of two or three, show definite signs of thyroid deficiency.

In one case a rat which had been maintained on a vitamin E-free diet for ten months had a litter of three, all of which appeared normal at birth, but which failed to grow, in spite of the fact that the mother was lactating freely. The appearance of the litter became increasingly cretinous; the head was large, the fur sparse and the nose upturned. The forepaws of one animal were abnormal, one foot being much larger than the other. The animals moved slowly and seemed to be of subnormal intelligence; they lived 17, 22 and 30 days respectively.

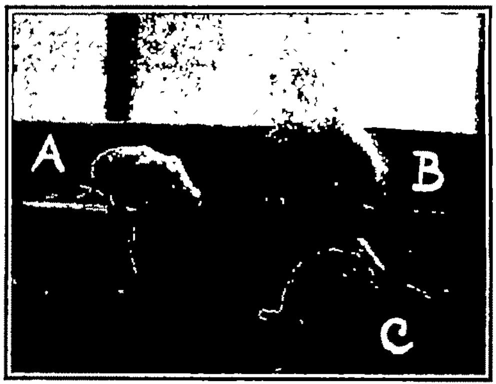

Fig. 1.

The second example was that of a litter of a rat which had been proved sterile and then dosed with a very small quantity of vitamin E concentrate. Again, three young were born, one died within the first few days and the other two gradually became cretinous, one dying at three and the other at four weeks of age. In one of the animals the feet were deformed, there being definite clubbing of the toes. One animal was very much smaller than the others, and post-mortem examination revealed two pink bodies in the position of the thyroid, but these showed no typical thyroid structure. The head was very large, and the fontanelles still widely open.

Fig. 1 shows a cretinous rat *C*, aged 21 days, and weighing 18·5 gm. with a normal rat *B* of 21 days, weighing 40 gm., and a normal rat *A* also weighing 18·5 gm. but aged only 10 days.

This complication of vitamin E deficiency is being investigated in greater detail, and will be fully reported in due course.

Protein Digestion of Wood-boring Insects

THE nitrogen supply of wood-boring insects has never been investigated. Ripper[1] assumes that it is derived directly from the wood. Mansour and Mansour-Bek[2] arrive at the same conclusion, and since their summary has been published, Parkin[3] has found a proteolytic enzyme in *Lyctus*, which supports this view.

During an investigation into the nutrition of the ash bark-beetle, *Hylesinus fraxini* Panz., which I am carrying out, I examined its protein digestion, and found it necessary to compare it with that of wood-boring beetles of different habitat. For this purpose a number of infested samples of wood was examined, and a comparative analysis of frass and wood carried out. The result is expressed in the accompanying table (numbers being percentages of dry weight of material):

Insect	Sample	Total N	Non-protein N	Protein N	Protein
Hylesinus fraxini Panz.	ash bark	0·54	0·08	0·46	2·88
	frass of larva	0·41	0·182	0·288	1·43
	frass of adult	0·68	0·326	0·354	2·21
Lyctus sp.	English oak sapwood	0·207	neglig.	0·207	1·30
	frass of larva	0·176	0·149	0·027	0·169
Anobium punctatum Geer.	Oak(?) heartwood	0·51	0·237	0·273	1·70
	frass of larva	0·345	0·170	0·175	1·09

The assimilation of nitrogen is really greater than appears here, as a considerable loss of weight occurs during the passage of material through the insect gut.

The frass of the *Hylesinus* larvæ consists of particles about the size of sand grains, and it is very probable that the gastric juices have thus no access to a large part of the protein, and so leave it unchanged. This applies to an even greater extent to the frass of the adult, which is much coarser, and only part of which passes through the gut at all. The rest, falling from the mouthparts, is, of course, altogether unattacked by gastric juices.

It is particularly interesting that the frass of the adult contains more nitrogen than the unattacked bark. The adult is therefore continuously decreasing its nitrogenous substance. This follows from the fact that the loss of weight by the conversion of wood into frass is very low and the increase of non-protein nitrogen is very large. This result is surprising in view of the fact that I found in the *Hylesinus* imago quite a strong trypsin and erepsin.

The *Lyctus* frass is exceedingly fine, and it is therefore not surprising that the protein is almost entirely broken down while passing through the gut.

In the case of the wood sample infested by *Anobium*, the high percentage of non-protein nitrogen is surprising. The reason for this is not known, but it can scarcely be connected with natural growth. Why such a high percentage of the protein remains here unattacked I cannot say, but I suspect that not all the chewed up material actually passes through the gut. Nothing is known about the presence and strength of proteolytic enzymes in this case.

Each of the values above is an average from a series of estimations. The numbers must still be regarded with reserve, as there is a considerable fluctuation in the different stages of the life-history, a question demanding further investigation.

I have also examined a sample taken from a deal chest, probably wood of *Abies* sp., infested by the Cerambycid *Hylotrupes bajulus* L. I had too little material to give definite results, but it seems that the original protein content of the wood is in the neighbourhood of 1·28 per cent, and that about 25 per cent of the nitrogen has disappeared in the frass.

The nature of the nitrogen compounds excreted seems to offer a wide scope for further investigations. Only in *Anobium* does uric acid play the main part. Though this compound is also present in the others, it does not account for all the protein broken down. In *Hylesinus*, a considerable amount of ammonia was found in the excretions, which has possibly been derived from uric acid by bacterial action. On the whole, the problem of excretion in the wood-feeding insects remains still entirely unsolved.

Jan Swammerdam

SINCE writing the sketch of Swammerdam which appeared in NATURE of February 6, p. 218, I have received some notes on the Dutch naturalist from that learned enthusiast Dr. H. Engel, of Amsterdam, which I hope he will publish in full in his forthcoming paper on the same subject. When I wrote my own contribution, I had not succeeded in obtaining a copy of the oration delivered by Prof. B. J. Stokvis at the celebration of the bicentenary of the death of Swammerdam held at Amsterdam in 1880. From this publication, and from Dr. Engel, I now learn that Swammerdam's grandfather was Jacob Dirksz. (= Jacob the son of Dirk, *ang.* Theodore or Richard), who was a wood merchant living in the village of Swammerdam, and it was he who migrated to Amsterdam and there adopted the name by which the great naturalist is known. Swammerdam's father, the apothecary, was therefore Jan or Johan Jacobsz. (= Jan the son of Jacob), and Swammerdam himself was baptized at the Oude Walenkerk of Amsterdam on Sunday, February 15, 1637, as Jan the son of Jan Jacobsz. Swammerdam and Baerta Jans Corvers. According to Harting, as quoted by Stokvis, Swammerdam's scientific career extended over twelve years only, from 1663 until 1675. It is improbable that he ever practised medicine. When he died, he was nearly forgotten, and it was the "magician" Boerhaave who brought to light his lost MSS. which gave immortality to the "sleeping beauty".

The statement so often made that Swammerdam's emotional obsessions were due to the influence of Anthoinette Bourignon seems to be an exaggeration. His friendship with her was the result, and not the occasion, of his deep interest in religion. The Dutch edition of the "Ephemeri Vita" testifies to his own innate and meticulous piety. Never was a sermon more deeply underlined or more laboriously justified. A scriptural basis for almost every word proclaims at once a profound knowledge of the Bible and an ingenuous belief in the literal interpretation of isolated texts.

Dr. Engel has found in Amsterdam an edition of the "Ephemeri Vita" published in Utrecht in 1699, a copy of which apparently does not exist in England. I also learn from him that the house where Swammerdam worked is still standing, and may be identified by a tablet erected during the celebrations of 1880. It remained in the possession of the family until 1716.

The decennial 'Swammerdam Medaille', also instituted in 1880, has been awarded to Siebold (1880), Haeckel (1890), Gegenbaur (1900), de Vries (1910), Max Weber (1920) and Spemann (1930).

Potential Constants of Tetrachlorethylene

G. B. B. M. Sutherland and D. M. Dennison[1] have deduced the relations between the parallel frequencies and the potential constants of the ethylene molecule from a given potential function; the following deals with the extension of these relations to a similar type of molecule, namely, that of tetrachlorethylene.

If from the data on Raman and infra-red spectra[2] we assume for the frequencies (Sutherland's notations):

$\nu_1 = 913$ cm.$^{-1}$; $\nu_2 = 445$ cm.$^{-1}$; $\nu_3 = 345$ cm.$^{-1}$; $\nu_4 = 1569$ cm.$^{-1}$; $\nu_8 = 236$ cm.$^{-1}$

and substitute these values in equation (*a*)

$$\nu_1^2 + \nu_2^2 + \frac{M+2m}{M} \; \frac{\nu_2^2 \; \nu_4^2 \; \nu_8^2}{\nu_1^2 \; \nu_3^2} = \nu_2^2 + \nu_4^2 + \nu_8^2$$

which has been deduced from the potential function, we obtain satisfactory agreement.

However, before computing the potential constants, it is necessary to modify the experimental values of the frequencies in order to satisfy equation (*a*) exactly.

A least square solution gave:

$\nu_1^* = 913$ cm.$^{-1}$; $\nu_2^* = 442$ cm.$^{-1}$; $\nu_3^* = 345$ cm.$^{-1}$; $\nu_4^* = 1569$ cm.$^{-1}$; $\nu_8^* = 230$ cm.$^{-1}$.

The smallness of the change of the experimental frequencies sufficient to verify equation (*a*) exactly should be noted.

Finally we find:

$a = 4{\cdot}59 \times 10^5$ dynes/cm.; $b = 1{\cdot}89 \times 10^5$ dynes/cm.
$c = 6{\cdot}15 \times 10^5$ dynes/cm.; $d = \pm 1{\cdot}52$ dynes/cm.

a, *b*, *c*, *d* being the potential constants.

The difference between my value of *c* (C–C bond) and Sutherland and Dennison's value for ethylene ($9{\cdot}79 \times 10^5$ dynes/cm.) is very remarkable. For this reason, I also used the Delfosse potential function[3], which is absolutely independent of Sutherland and Dennison's. Furthermore, I used only the three Raman frequencies ν_2, ν_4, ν_8, which are much more certain than the ν_1 and ν_3 necessary in Sutherland and Dennison's theory. This ought to give more weight to the following results.

We find:

$F = 6{\cdot}25 \times 10^5$ dynes/cm.; $\gamma = 2{\cdot}24 \times 10^5$ dynes/cm.; $f = 1{\cdot}28 \times 10^5$ dynes/cm.

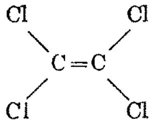
f and *F* are respectively proportional to the C–Cl and C–C distances; γ is a force proportional to the angle variation Cl–C–Cl.

The agreement between the two values of the C–C strength bond is very striking. It should be noted that the value γ is greater than *f*. This is contrary to ordinary chemical conceptions. The difference between the C–C value for ethylene and tetrachlorethylene agrees qualitatively with Badger's formula[4]

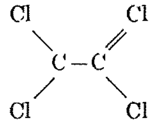
$$r_e = (C_{ij}/k_e)^{1/3} + d_{ij},$$

which shows a very definite relation between the force constant k_e for a particular bond and the internuclear distance r_e associated with that bond. Consequently, if the force constant is smaller in C_2Cl_4 than in C_2H_4, the C–C distance should be larger in C_2Cl_4 than in C_2H_4. Electronic diffraction and spectroscopic measurements do not invalidate this deduction. L. O. Brockway[5] gives 1·38 A. for tetrachlorethylene, W. Scheib and P. Lueg[6] 1·34 A. for ethylene. The C–C distance deduced from Badger's formula is too small. However, Penney and Sutherland[7] have shown that considerable divergences exist from the formula in other compounds.

If the force constant is real, its variation might be due to the fact that tetrachlorethylene is a combination of molecules showing quite different structures, as for example:



,



In that case, the C–C value would be a sort of resonance between the double and single bonds.

These considerations do not, however, exclude the possibility that this molecule cannot be treated in the same way as C_2H_4.

In the preparation of this note, I am especially indebted to Prof. V. Henri for his personal attention, and to Dr. G. B. B. M. Sutherland for correspondence.

Raman Spectra of Oxonium Compounds

The study of the Raman spectra of oxonium compounds is of interest for the elucidation of the nature of the oxonium bond. Such a study was made by Briegleb and Lauppe[1], who investigated the spectra of mixtures of ethyl ether with hydrogen bromide and stannic chloride. However, their work does not give a clear and unequivocal answer to the question of the nature of such compounds. We have undertaken the study of the oxonium molecule $(CH_3)_2O.HCl$, which is known to exist even in the gaseous state. The equilibrium between methyl ether and hydrogen chloride has been studied in the vapour state with sufficient exactness[2]. It cannot be doubted, therefore, that $(CH_3)_2O.HCl$ exists as an individual molecule. We have obtained for $(CH_3)_2O$ in the liquid state, at 280° K., the following frequencies: 408 (2) (*e,k*); 921 (6*d*) (*e,k,i*); 1095 (1) (*k*); 1448 (2*d*) (*e,k*); 2813 (10) (*e,k,q,p*); 2868 (3) (*e,k,i*); 2908 (3) (*e,k,q*); 2947 (2) (*e,k,q*); 2988 (6) (*e,k,q,p*).

These data agree well with the results of Kohlrausch[3]. We have investigated the spectra of equimolecular mixtures of methyl ether, $(CH_3)_2O$, and hydrogen chloride at 280° K. in the liquid state. We obtained the following frequencies: 418 (3) (*k*); 891 (4*d*) (*e,k*); 1081 (1) (*k*); 1449 (1*d*) (*e,k*); 2829 (7) (*e,k,q*); 2875 (2) (*e,k*); 2923 (2) (*e,k,q,p*); 2953 (2*d*) (*e,k,i*); 3003 (5*d*) (*e,k,q*).

The same mixture was investigated at low temperatures down to 220° K. No shift at all could be observed in comparison with the spectra at 280° K. The comparison of the spectra of $(CH_3)_2O.HCl$ with the spectra of $(CH_3)_2O$ shows the absence of new lines. It may, however, be stated that displacements were noticed in a series of frequencies that were greater than the error of the experiments (~ 5 cm.$^{-1}$). Of the greatest interest is the decrease of the frequency

$\nu(\pi)$ of $(CH_3)_2O$ from 921 cm.$^{-1}$ to 891 cm.$^{-1}$. Evidently it is caused by the bond between the ether oxygen with HCl. Our results contradict the supposition that the valency of the oxygen is increased; since in this case the molecular model would be changed, which would change the number and magnitude of the fundamental frequencies. It may be supposed that the bond between the ether oxygen with HCl belongs to the hydrogen bond type[4], that is, we do not have the usual O–H bond with a distance of 1 A. and corresponding frequency 3600 cm.$^{-1}$ but rather a bond of an intermediate type between the chemical and the Van der Waals forces with a distance of the order of 1·3 A. between O and H.

The dispersion of our spectrograph is too small to distinguish between the proper frequency of HCl and the very close frequencies of the CH_3 group[5]. However, a detailed study of the photometric curve obtained with a Zeiss microphotometer did not show any change which could be attributed to the line of HCl. Its absence apparently indicates the strengthening of the heteropolarity of HCl, which can make this line forbidden, in the Raman spectra.

The measurements of specific electric conductivity of a mixture of 0·41 molar hydrogen chloride and 0·59 molar ether at 253° K. gives 0·0034 Ω^{-1}. This indicates insignificant dissociation.

Besides the compound described above, we have investigated the complex $(C_2H_5)_2O.HCl$, in the spectra of which we were unable to find any change in comparison with the spectra of $(C_2H_5)_2O$. We also studied $(CH_3)_2O.HBr$, but it was impossible to obtain the spectra of the oxonium compound because of a very fast reaction with the formation of CH_3Br.

The detailed account of this work will be published in the *Acta Physicochimica U.R.S.S.*

Factors influencing the Height of the Combustion Levels attained in Flame Gases

DURING the past seven years, many hundreds of measurements of the combustion levels[1] in flames and explosions have been made. They range from 70 to 99 per cent of the heat of combustion, and without exception they fit into the following analysis of the factors which tend to heighten or lower them.

For convenience of presentation, the inflammable mixtures selected for purposes of illustration are those which after combustion yield a theoretical temperature of 1,900° C. when calculated upon the basis of the quantum specific heats.

(1) *Influence of the nature of the combustible gas.* Temperature measurements in flame gases after combination at constant atmospheric pressure yield the following combustion levels[2]:

CO-air	CH_4-air	C_2H_2-air
80 per cent	83·5 per cent	85 per cent

So far as our experiments have gone, the highest combustion level is attained in C_2H_2-air mixtures.

(2) *Influence of the nature of the diluent gases.* The flame temperatures were measured after combination at constant atmospheric pressure. Attention is directed to the low combustion level attained with argon as the diluent gas.

CO-O_2-A	CO-O_2-CO_2	CO-air
72 per cent	77 per cent	80 per cent

(3) *Influence of small quantities of diluent gases in certain cases.* The mixtures carbon monoxide-oxygen-nitrogen and carbon monoxide-oxygen-argon, in which carbon monoxide and oxygen are present in combining proportions, yield lower combustion levels than similar mixtures in which a small quantity of the nitrogen or argon is replaced by oxygen.

As a result of a discovery by Wohl and von Elbe, it has been found that there is an appreciable raising of the combustion level in hydrogen-air explosions by the addition of a small quantity of water vapour[3]. Additions of water vapour to carbon monoxide-air mixtures, while they speeded up the explosions, had no very large influence upon the combustion levels attained.

(4) *Influence of pressure at which constant pressure combustion takes place.* The following combustion levels were measured in carbon monoxide-air mixtures burning at pressures of 1 atmosphere and 5 atmospheres:

1 atmosphere	5 atmospheres
80 per cent	86·5 per cent

The increase with pressure of the combustion level in methane-air mixtures was not nearly so marked as in the case of carbon monoxide-air and acetylene-air mixtures[4].

(5) *Influence of the instantaneous pressure in the flame front.* It was shown in a recent letter to NATURE[5] that from an examination of the intensity of the after-glow resulting from the passage of flame through a long open tube, it appeared that the combustion level increased with distance of flame travel and therefore with the instantaneous pressure in the flame front. The flame gases in which the measurements referred to in (1), (2) and (4) were made corresponded to those left behind the initial slow flame movement. The combustion levels measured are therefore probably the lowest attainable in the mixtures.

(6) *Combustion levels in large vessel explosions.* The explosions were made in a large spherical vessel fitted with electrodes for central ignition. During the initial slow movement of the flame after the passage of the spark, the flame gases have combustion levels as given in (1), (2) and (4). Later, the instantaneous pressure in the spherical flame front begins to increase and the combustion level in the gases left behind becomes greater and greater. The flame gases in the central portion constitute only a small proportion of the total gases and it is therefore clear that the combustion level averaged over the whole of the exploded gases must be high. In an over-rich carbon monoxide-oxygen mixture initially at 3 atmospheres pressure, the combustion level averaged over the whole of the exploded gases was found to be as high as 99 per cent. In low density explosions it is considerably less[6].

It will be clear that the combustion level in any given mixture may be raised by increasing the pressure of the gases before combustion or by arranging for high instantaneous pressure in the flame front, or both—as in high-density explosions and in internal combustion engines. Interesting possibilities also are suggested by the fact that a little water vapour increases the combustion level in hydrogen explosions.

Physical Constants and some Curious Coincidences

Many comments have been made on the nearness of a certain constant in modern physics to the number 137, but I have seen no comments on the following coincidence.

The velocity of light *in vacuo* is $2 \cdot 99774 \times 10^{10}$ cm. a second, and the gravitation constant is $6 \cdot 670 \times 10^{-8}$ in C.G.S. units; the first of these is therefore just a little less than 3×10^{10} and the second just a little greater than $\frac{2}{3} \times 10^{-7}$, both interesting coincidences with simple numbers in themselves, but the product of those numbers is 1,999·5, a remarkably close approach to 2,000. The product is, however, not a 'mere number' and the coincidence must therefore depend upon the relative magnitudes of the C.G.S. units.

Curiously enough, if both the above physical 'constants' are expressed in English units, the product is 1·05, a very near approach to unity—another coincidence.

Points from Foregoing Letters

Prof. E. M. Fraenkel and Dr. C. A. Mawson report that although they are able to deposit the agent of the Rous fowl sarcoma by centrifugation at 15,000 r.p.m., they are unable to correlate the cancer-producing activity of the extracts and concentrates with the number of ultra-microscopic particles present, and suggest that only a fraction of the visible particles are associated with carcinogenic activity. They have been unable to obtain tumours by injection of acetone extracts of fresh or dried tumour tissue, but the residue left after the extraction of dried powder retains its carcinogenic properties.

New electrical measurements of the oxide films responsible for interference colours on copper and iron, announced by Drs. U. R. Evans and H. A. Miley, show satisfactory agreement with three other methods. Thus tested, the method has been used to study the rapid growth of invisible oxide on copper at 18° and 62° C. The results accord well with recent electron diffraction work by Dobinski.

The exchange of iodine atoms between organic compounds containing such atoms and sodium iodide or iodine itself, at a temperature of 100° C. in various solvents, has been investigated by H. A. C. McKay, by utilizing radioactive iodine as indicator. The author describes the behaviour of the higher alkyl iodides, (ethyl, propyl, isopropyl, butyl and isoamyl iodides), iodoacetic acid, β-iodopropionic acids and of some aromatic compounds (phenyl iodide, *p*-nitroiodobenzene, *p*-iodoaniline and *p*-iodobenzoic acids).

A table is submitted by Dr. L. H. N. Cooper, showing that the order in which acidic ions are arranged in the Hofmeister (lyotropic) series, which indicates their effectiveness in the swelling of gels, flocculation of sols, etc., runs parallel to the order of their (Gibbsian) standard free energies of formation from their elements. The free energies of formation of the halide ions are proportional to their electrode potentials, so that the effect may possibly be explained by the relative readiness of the ions to part with their electrons.

An example of the power of light of different wave-lengths (near and middle ultra-violet) to shift in opposite directions the equilibrium of a thermal oxidation-reduction reaction is described and discussed by G. Holst. The system considered consists of methylene blue (A)—leucomethylene blue (AH_2) and phenylhydrazinesulphonate (BH_2)—benzenediazosulphonate in dilute acid solutions, the photo-active absorption of AH_2 being situated in the near ultra-violet, and that of BH_2 in the middle ultra-violet.

Dr. A. B. Wildman states that many fleece analyses indicate the existence of gradients over the fleece in mean fineness and fleece density. Such results are consistent with the idea of increased physiological activity in the skin anteriorly, and form evidence in addition to that of Dr. Galpin's for the existence of a main antero-posterior gradient in wool growth.

Symptoms of cretinism, a disease associated with the absence of the thyroid gland, are described by Miss M. M. O. Barrie in young rats deficient in vitamin E.

H. S. Hopf compares the nitrogen contents of the frass of wood-boring insects with that in the wood on which the insects feed. The results indicate that the larvæ retain much of the nitrogen from the wood, but the adult of the ash bark-beetle appears to be continuously decreasing its nitrogenous substance.

Jules Duchesne compares the values of the parallel frequencies calculated from the Raman and infra-red spectra of tetrachlorethylene, with those necessary to satisfy the relation deduced from the 'potential function' by applying the formula of Sutherland and Dennison. The author calculates the forces linking different atom groupings in the C_2Cl_4 molecule and finds the result at variance with the ordinary chemical conception of its structure.

From a study of the Raman spectra of ethyl ether and hydrochloric acids in equimolecular proportions, M. Wolkenstein and Prof. J. K. Syrkin conclude that the valency of oxygen in the oxonium molecule is not increased. The bond between the ether oxygen and HCl is of a type intermediate between the chemical and the Van der Waals forces, with a distance of the order of 1·3 A. between the oxygen and hydrogen atoms.

Various factors influencing the 'combustion level' (ratio of maximum observed temperature to the theoretical temperature) in flames and explosions are discussed by Prof. W. T. David. These include the influence of the nature of the combustion gases, of the diluent gases, size of vessel, etc. The combustion level may be raised by increasing the pressure of the gases before combustion or by arranging for high instantaneous pressure in the flame front.

Research Items

Homo modjokertensis

DR. E. DUBOIS, in a recent communication to the Koninklijke Akademie van Wetenschappen te Amsterdam (*Proceedings*, 39, 10), sets out his reasons for regarding this skull, found in February 1936 in the early Pleistocene deposits of Modjokerto, Java, as an infantile form of the same race as that found at Ngandong, to which the specific name *soloensis* has been given. The striking fact about the skulls of Solo man is the low brain capacity, which in the largest male has been calculated at 1,295 c.c., barely equalling the male Australian, while the largest female (probable) is put at 1,095 c.c. The adult of Modjokerto cannot have been more than *Sinanthropus* I, which is 915 c.c. The Modjokerto skull itself probably has a capacity of 650 c.c., agreeing with a Papuan child of two years, which would give a capacity in the adult of 900 c.c., approximating to *Sinanthropus*. This and other facts bring together *pekinensis* and *soloensis*. As to the racial identity of Solo man and Modjokerto man, there can be no doubt. In both there are peculiarities due to the necessity of poising the head on the vertebral column. The similarity in the brain of Peking man and of Solo man is striking. The contour lines in norma lateralis nearly coincide. The conclusive proof, however, is in the unique morphology of the tympanic portion of the temporal bone. The meatus acusticus externus is not directed forward, as in all the modern races, and Neanderthal and Rhodesian man, but transversely and somewhat backward. The tympanic plate is exceedingly thick and strong, the forward part being more or less convex, and not concave as in the modern. The border of the porus acusticus externus shows a peculiar re-entering, which in *Sinanthropus* is continued in a roundly terminating fissure, strikingly resembling such a fissure in a young, probably less than one year old, Papuan child. Finally, if Modjokerto and *pekinensis* are both early Pleistocene, may not Solo man also be early Pleistocene? The evidence for late Pleistocene is unsubstantial.

Fauna of Singapore

THE *Bulletin* of the Raffles Museum, Singapore, Straits Settlements, No. 12, May 1936 (issued December 1936) contains much that is interesting relating to the fauna of Singapore and adjacent waters. A list of the fishes in the collection of the Raffles Museum is given by the curator, Mr. M. W. F. Tweedie, and eleven new species from the Malay Peninsula are described and illustrated by Mr. W. P. T. Hesse. The fishes of this district are of great interest; not only are there many new species to be found, but also it may be considered as a halfway point between the Red Sea and the east coast of Africa, and the isles of Polynesia. The fishes of China and India commingle and, as the author's recent collections show, many fishes hitherto known only in the Philippines also occur on the reefs and in the creeks of Singapore and Johore. The migratory fishes of the Indo-Pacific pass Singapore, and its reefs swarm with a rich and varied fish fauna. There are several papers dealing with the Crustacea, especially freshwater decapods, and with marine crabs of the family Grapsidæ mainly collected in the mangrove swamps. Among the freshwater decapods is *Palæmon* (*Parap.*) *trompi* de Man subsp. *armatus* n. subsp. from Johore, which hitherto was only known from Borneo, and which lives in the same waters as *Palæmon pilimanus* de Man. The eggs are large and few in number, but apparently nothing is known of its life-history. Among the other contributions are two papers on "Nidification of some Javan Birds" by A. Hoogenwerf, and "The Nidification of some Malayan Birds" by G. C. Madoc. Both contain much original observation, and the first is illustrated with very beautiful photographs.

Chemical Carcinogenic Agents

AN extremely valuable summary of the last three years work on chemical compounds as carcinogenic agents by J. W. Cook, G. A. D. Haslewood C. L. Hewett, I. Hieger, E. L. Kennaway and W. V. Mayneord ("Reports of the Second International Congress of Scientific and Social Campaign against Cancer"; Brussels, 1936) shows that there is a large number of pure chemical compounds which produce cancer in animals. The most active compounds, such as methylcholanthrene, cholanthrene and 3 : 4-benzpyrene, produce epitheliomata of the skin when painted on mice and sarcomata when injected subcutaneously in either rats or mice. Reference is made to the discovery by Sasaki and Yoshida of the action of amino-azo-toluene, which produces cancer of the liver and bladder when fed to animals. Amino-azo-toluene is a commercial orange dye used for varnishes, fats, margarine and leather. It has also been recommended for medicinal use to promote the growth of skin on wounds. Carcinogenic hydrocarbons are fat-soluble; but water-soluble carcinogenic compounds have been described. The sodium salt of 1 : 2 : 5 : 6-dibenzanthracene-9 : 10-endo-$\alpha\beta$-succinic acid, produced by combination of 1 : 2 : 5 : 6-dibenzanthracene with maleic anhydride, produces sarcomata on injection in mice, and some of these sarcomata are accompanied by leucocytosis in the blood. A water-soluble quinoline styryl compound which was originally tested for trypanocidal action was found by Prof. C. H. Browning to cause the development of cancer in mice whether the mice are infected with trypanosomes or not. The natural female sex hormone œstrin induces cancer of the mamma and adenoma of the pituitary, although not of the skin when it is painted on mice. The mechanism of carcinogenesis is still not clear, but such work as has been done to increase understanding of the process emphasizes the importance of the species, strain and sex of the animals employed.

The Asparagus Fly

THE asparagus fly (*Platyparea pœciloptera* Schr.) is a native of central and southern Europe, but it appears to be moving slowly westward, and since the beginning of this century has become a serious pest in the valley of the Seine. It was first reported in Holland in 1931, and four years later it appeared in England. In view of the possibility of its further spread, the illustrated account of the life-history of the fly with recommendations for its control given by A. S. Buckhurst (*J. Min. Agric.*, 43, No. 10) will be useful to both the private and commercial grower of asparagus. The damage is done by the larvæ which tunnel in the stems, so that either the young edible shoots are spoilt or the later growth weakened according to the time of emergence of the flies. The latter is considerably earlier on the Continent than in England, but the period during which the flies are on the wing extends to about six weeks in both cases. There is only one generation in the year, the pupæ over-wintering in the stems at or below ground-level. So far, no entirely successful method of control has been found, as traps are only partially effective and spraying is not an economic proposition. To remove and burn all distorted stems as early as possible in the autumn, taking care to cut as near the crown as possible, is the best method at present known for reducing the trouble, but even then many of the pupæ escape destruction. Experiments are in progress with the view of finding a soil insecticide which will eradicate the pest more thoroughly, but although small-scale trials are giving promising results, no definite recommendations can as yet be made.

The Cape Crawfish

LITTLE was known of the development of this crustacean, although much has been written on its anatomy. Dr. C. von Bonde in his recent work "The Reproduction, Embryology and Metamorphosis of the Cape Crawfish (*Jasus lalandi*) (Milne Edwards) Ortmann" (Department of Commerce and Industries. Fisheries and Marine Biological Survey Division. Investigational Report. No. 6. Union of South Africa, Government Printer, Pretoria, 1936) now gives us a good account of the reproductive and developmental stages, which are described in detail, and at the same time certain facts relating to the post-ovum stages in the description set forth previously by Gilchrist are substantiated or corrected. Part 1, on reproduction, deals with sexual differences and reproductive organs, sperm cells and ova, period of sexual maturity, frequency of spawning, mating, preparation for egg laying, fertilization of the eggs and attachment of eggs to the abdomen. Part 2, on embryology, deals with the maturation and segmentation of the ovum and later embryological stages. Part 3 deals with metamorphosis and subsequent growth and Part 4 with technique. The author has in preparation a further paper on the phyllosoma stages obtained by artificial hatching and rearing, but in the present work it is shown that the larva hatches at a stage still younger than that described by Gilchrist (1913) as the nauplisoma. Stage III is a true phyllosoma, and numerous stages occur between those of 3·8 mm. and 24 mm. to be described later. At 35 mm. the last phyllosoma changes to the puerulus stage of 22 mm. "which appears in all essentials to be like a small adult and the appendages including the pereipods (but excluding the pleopods) are adult-like in form". The stage immediately following the puerulus resembles the adult still more, and this may be regarded as the youngest stage of the fully-formed crawfish. The paper is illustrated by photographs and by two coloured plates of the developing embryo

Nerve Fibres in Cephalopods and Crustaceans

THE structure of the nerve fibres in cephalopods and a crustacean, *Maia*, has been investigated by J. Z. Young (*Proc. Roy. Soc.*, B, Dec. 1936). In the former, each axial fibre is furnished with a nucleated sheath of a collagenous nature. Faint longitudinal striation is visible in both living and fixed fibres, but no neurofibrils are present. Indeed, if a giant nerve fibre is cut, the axoplasm flows out from the sheath, showing it to be a viscous fluid. The volume of the sheath is in general only about two thirds that of axoplasm. In *Maia*, each axon is surrounded by a connective tissue sheath which contains a certain amount of fat, but it is not similar histologically to the medullated sheath of the vertebrate nerve, although this has previously been stated to be the case. The sheath is slightly thicker relative to the axon than in the cephalopods.

Endemic Flowering Plants of the British Isles

A CONSIDERABLE number of floral units—mostly sub-specific—are now recognized as endemic to the British Isles. In a discussion of the problems which they present, Wilmott (*South-Eastern Naturalist and Antiquary*, 41; 1936) suggests that hybridization is a probable cause of the origin of endemism in some groups. Thus, the numerous endemic mossy saxifrages of western Ireland may have arisen through original crosses between the Arctic *S. cæspitosa* and the Atlantic *S. hypnoides*, which were brought together as a result of migrations imposed by the glacial period. Evidence is adduced to show that other Irish endemics are pre-glacial survivors, but in the case of the Hiberno-American *Spiranthes*, it is difficult to believe that whilst the southern Irish plant is a survivor its very close ally in the north is a recent immigrant, as is suggested. As regards British endemics, a correlation is attempted between their distribution in relation to areas of glaciation. It is shown that whilst some occur in areas which were not glaciated, others, for example, *Sorbus* spp. and *Helianthemum Breweri*, grow on cliffs which might be presumed to be free from ice in the summer, and the view is expressed that they also represent relatively ancient elements of the flora.

Production of Polyploid Plants

THE subject of polyploidy in plants has grown so rapidly and has become of such importance in connexion with plant genetics that the recently issued bulletin of the Imperial Bureau of Plant Genetics on "The Experimental Production of Haploids and Polyploids" will be very useful for plant breeders (Imperial Bureau of Plant Genetics for Crops other than Herbage. The Experimental Production of Haploids and Polyploids. Pp. 28. Cambridge: School of Agriculture, 1936. 5*s*.). The production of allo- and autopolyploids is one of the most important methods of producing new basic types of economic plants. The bulletin briefly summarizes the cases of polyploidy in somatic cells and the production of polyploid cells by changes in temperature, the use of X-rays, chemicals, centrifuging, tumours and shoots from callus. Polyploid gametes have been produced by similar methods including fumigants, attack of pests, puncturing the buds and virus mosaic. Polyploidy resulting from hybridization is recorded in a large variety of plants, with a long list of cases especially in wheat and tobacco. It is probable that the experimental production of haploids and polyploids will become a matter simply of selecting the best technique for each case. The bibliography, while merely representative, comprises nearly 300 entries including certain references to non-economic plants.

Resistance of Cotton to the Wilt Fungus

A SHORT paper by Dr. B. B. Mundkur (*Proc. Ind. Acad. Sci.*, **3**, No. 6, Sec. B., 1936) gives the results of some experiments on the resistance of Indo-American and Indian varieties of the cotton plant, *Gossypium hirsutum*, to the fungus causing wilt disease (*Fusarium vasinfectum*). Two forms of the fungus evidently occur, an Indian and an American strain. Indo-American cottons are immune to the American strain in India, but susceptible in America, whilst the Indian form of the fungus parasitizes Indian cottons strongly in India, but only slightly in America. It seems as though the fungus had developed one geographical strain capable of parasitizing the host when grown on the sandy and acid American soils, and another strain to fit the particular physiology of the cotton plant when cultivated upon the heavy alkaline soils of India.

Low Temperature Thermometry

WHILE the practical methods of making measurements of temperature which approximate closely to the standard thermodynamic scale are now quite accurate enough for industrial purposes, it is still necessary for scientific purposes to secure greater accuracy in the region in which helium is liquid. At the Congrès International du Froid held at Amsterdam in June last, Prof. Keesom gave an account of the present position of the problem, which has now appeared as Supplement No. 80 of *Communications from the Kamerlingh Onnes Laboratory* of the University of Leyden. In NATURE of December 5, p. 977, the Leyden value of the pressure coefficient of helium, 0·0036611, and the absolute zero to which it leads, − 273·14° C., were given. Between 0° and − 190° C., the platinum resistance thermometer is correct to 0·05° C., but for greater accuracy it will have to be replaced by some other metal, possibly gold. For the range − 190° C. to − 259° C., a formula of correction secures an accuracy of 0·07° C. Temperatures below this down to about 2° K. are measured by the vapour pressure of liquid helium, and lower still by the resistance of a phosphor bronze wire containing 2 per cent tin and 0·05 per cent lead. This, however, becomes unsuitable in magnetic fields, and further research is necessary to find an alloy less influenced by such fields.

Entropy of Sulphur

THE determination of the heat capacities of rhombic and monoclinic sulphur at low temperatures, leading by graphical integration to the entropies of the two forms, is of interest as a check on the third law of thermodynamics. E. D. Eastman and W. C. McGavock (*J. Amer. Chem. Soc.*, **59**, 145; 1937) have redetermined the heat capacities over the range 15°–375° K. and have calculated the entropies. The values of C_v for rhombic sulphur may be represented approximately up to $C_v = 3{\cdot}0$ by the function $f\,(T/\theta)^n$, proposed by Lewis and Gibson, if $\log \theta = 1{\cdot}992$ and $n = 0{\cdot}5025$. From previous determinations of the heat of transition the authors select the value 0·258 ± 0·027 e.u. at the transition point. From the entropies now determined, the value 0·215 ± 0·05 at the same temperature is calculated. The conclusion is drawn that the third law is accurately applicable, without complications of the types that sometimes occur, to the sulphur transition. The uncertainty of 0·05–0·10 e.u. in this test of the law is stated to be smaller than that in many others, and it is claimed that the experimental basis of the third law, as supported by the sulphur transition, is strengthened by the new results.

Deuterium Content of Normal Water

THE ratio of deuterium and protium, D/H, in normal water has been given between the rather wide limits of 1 : 5600 and 1 : 8900. J. L. Gabbard and M. Dole (*J. Amer. Chem. Soc.*, **59**, 181; 1937) have prepared deuterium-free hydrogen by electrolysis of water to which sodium peroxide had been added, and combined it with atmospheric oxygen by passing over heated copper with the hydrogen always slightly in excess to prevent fractionation of the oxygen isotopes. The resulting water was 9 p.p.m. lighter than Lake Michigan water. When 6·4 p.p.m. are added to 9 p.p.m. to correct for the difference in atomic weight of atmospheric oxygen and aqueous oxygen, the density of D-free water containing normal oxygen is 15·4 p.p.m. lighter than normal water. From this the ratio D : H (atoms) in Lake Michigan water is calculated as 1 : 6900. The authors conclude that the commonly accepted ratio is too high, and the revision downward should be somewhat more than that recommended by N. F. Hall and T. O. Jones (1936).

Velocities of Meteor Streams

IN a paper published early last year (*Mon. Not. Roy. Astro. Soc.*, **96**, 7; May 1936) Mr. R. A. McIntosh described a method of determining the velocities of meteors by measurement of the displacement of the radiant as observed in northern and southern latitudes. He provided two tables to facilitate the computations, and the method presents certain attractive features. In the November issue of the same journal (**97**, 1; 1936), Dr. M. Davidson shows that there is a serious error in the method of compilation of the first of Mr. McIntosh's tables, and that this renders the whole process useless.

Internal Constitution of Eclipsing Binaries

IN *Mon. Not. Roy. Astro. Soc.*, **96**, 9, Supplementary Number, October 1936, there is a paper with the above title by Zděnek Kopal, the object of the research being the determination of the density concentration in the interior of stars, starting with eclipsing binaries as material. The ellipticities of the components were used by Walters, but an unfortunate error vitiated some of his quantitative results, as pointed out by Kopal. He deals with the problem very fully, and concludes that the density concentration depends on the age of the system, the components of a new-born binary being nearly homogeneous. The density concentration becomes appreciable in the course of the evolution of the system, until finally both components come close to the model requiring a high density concentration. With advancing spectral type there is an increase in the density concentration, and here we may find something of fundamental physical significance. If it be assumed that stellar energy originates in the formation of heavy elements out of simple ones, we must expect an increase in the number of heavy atoms as the star ages, and these will sink to the centre. If future investigation should confirm this view, there will be some evidence in favour of the theory of the transmutation of elements in stellar interiors. It is suggested that the results may be generalized for spectroscopic binaries.

Early Man in Java

A COMMUNICATION by Dr. P. V. van Stein Callenfels to the Royal Anthropological Institute, which appears in summary form in *Man* of December, urges the desirability of reconsidering the age and standing of *Pithecanthropus*. Dr. Callenfels has classified the fossil fauna of the Java Pleistocene into three groups—early, middle and late Pleistocene. Among those of the early Pleistocene are *Stegodon cf. præcursor* (between Tertiary *præcursor* and Middle Pleistocene *trigonocephalus*), *Hippopotamus antiquus*, *Leptobos*, three antelopes and marine molluscs, of which at least 30 per cent are extinct; Middle Pleistocene *Stegodon trigonocephalus*, *Hippopotamus namadicus*, *Bos* (*Bubalus*) *bubalis palæokarabau*, *Axis axis lydekkeri* (abundant), *Duboisia* (antelope); Late Pleistocene *Stegodon trigonocephalus*, *Hippopotamus namadicus*, *Bos* (*Bubalus*) *Axis axis lydekkeri* (very rare), *Axis axis javanicus* (abundant).

By the associated fauna *Pithecanthropus* belongs to the Middle Pleistocene and Solo man to the late Pleistocene. In February last, however, a fossil skull of a child between one and three years was found at Modjokerto, which belongs somewhere in the line of human development. It may have been an infant *Pithecanthropus*. It belongs to the oldest Pleistocene. The discovery of a skull of this age necessitates raising the whole *Pithecanthropus* problem. No fossil fauna of the oldest Pleistocene survives into the Middle Pleistocene and it is, therefore, unlikely that the hominoid only should have survived. The Middle and Late Pleistocene have most of the animals in common, so that Solo man, known from one site only, may have existed in Middle Pleistocene times.

The records of the discovery of the femur of *Pithecanthropus*, which was made by Dubois himself, are known; but of the discovery of the skull-cap, which was made by a sergeant, the record has not been preserved. It is possible that the skull-cap is older than the femur. It may belong to the same stratum as the infant skull, while the femur is that of Solo man. The stone and bone artefacts discovered with Solo man clearly must belong to late Pleistocene; but implements recently discovered at Patjitan by Dr. G. R. H. von Kœnigswald, identical with Chellean and Clactonian, are so different as to suggest that they cannot have been made by the same type of man.

In this connexion attention may also be directed to a discussion by Prof. E. Dubois of *Pithecanthropus* and other early forms of man from Java which appears in *Man* of January. Prof. Dubois proceeds by setting out two propositions which he supports by argument.

Proposition I. Homo soloensis is human and proto-Australian, forming with Rhodesian man, who closely resembles Solo man, a proto-Australian group representing the most primitive type of *Homo sapiens* and distinct from *Homo neanderthalensis*, the other human species.

Wadjak man is also proto-Australian, and was described as such so long ago as 1920, though its character was recognized when it was first discovered in 1890. The distinguishing characters which determine this classification of Rhodesian man, notwithstanding its gorilloid qualities, are the pulp cavities of the teeth, the slender limb bones, the peculiar nuchal plane of the occipital bone, and the low cranial capacity, the size of the brain approaching but not quite equalling that of the Australian. The form of the *torus supraorbitalis* in Rhodesian man is of the type of the supraorbital ridge of the Australian rather than of the torus of Neanderthal man. The resemblance of Solo man to Rhodesian man is most striking.

H. soloensis and *H. rhodesiensis* then, with *Sinanthropus*, are the most important of all known fossil men, as representing the most primitive type of *H. sapiens*. The Australian aborigine has conserved much of the primitive somatic character, especially the fundamental and, therefore, most distinctive quality of the mammalian organism, the characteristic brain volume. In the Australian (male) this may be taken as averaging 1,295 c.c. The cubic capacity of the brain of Rhodesian man has been calculated as 1,280 c.c., and for Solo man in the skull Ngandong I as approximately 1,200 c.c. The proto-Australian of Ngandong and the proto-Australian of Rhodesia both had brains which were a little smaller than the brain of the Australian of to-day.

In regard to age, a very recent age is to be attributed to the deposit in which Rhodesian man was found, while fossil Solo man is of post Trinil geological age.

Proposition II. Pithecanthropus was not a man, but a gigantic genus allied to the gibbons, superior to its relatives on account of its exceedingly large brain volume, and distinguished at the same time by its erect attitude.

Decisive evidence in support is afforded by the four new femora which were recognized in the Trinil collection in 1932. Corrosion in these, by removing the superficial or periosteal bone layer, has laid bare the internal structure of the shaft wall. This deeper shaft structure is entirely different from the human, and betrays a muscular function and a locomotion, which though facultatively erect and human-like on the ground, was also arboreal, and perhaps on uneven ground a perfection of the semi-erect gait of the gibbon. Thus this new evidence of the morphological and functional distinctness of *Pithecanthropus* furnishes proof at the same time of its close affinity with the gibbon group of anthropoid apes.

The gibbon-like appearance of *Pithecanthropus* is evident from the general form and many morphological details of the skull. It is evident, for example, that the gravitational centre of the head was a considerable distance in front of the condyles, and hence there was no parietal vertex of the brain, a distinctive character of man. Here *Pithecanthropus* agrees with chimpanzee and gibbon. The head was not poised on the vertebral column. The mandible most resembles that of the gibbon, so far as its features are anthropoid, while the strongest evidence is that given by the volume of the cerebrum, which on the law worked out by Prof. Dubois, regulating cerebral quantity in mammals, entirely confirms this second proposition.

Prof. Dubois adds a postscript dealing with the fossil child's skull discovered in February 1936, and described under the name of *Homo modjokertensis*. In another context it has been called "the oldest datable human fossil". In the opinion of Prof. Dubois, however, it is a child of *Homo soloensis*, the proof of identity being the similarity of the peculiar tympanum (see also p. 291).

The Lochaber Water Power Scheme

AN article on "The Lochaber Hydro-Electric Power Undertaking", in NATURE of November 29, 1930 (126, 848–849), described the first and main portion of an engineering scheme of considerable magnitude by which water from a catchment area of 303 square miles in Inverness-shire is being collected and led to a power station at Fort William, near the foot of Ben Nevis, which will have an ultimate capacity of 120,000 horse-power—by far the largest installation of its kind in Great Britain. The first instalment of the undertaking, costing about three million sterling, utilized the natural reservoir in Loch Treig by means of a tunnel pipe line to Fort William, and was completed in 1930. The second in the sequence of three stages of development was commenced shortly thereafter and completed in 1934, at a cost of another million. It forms the subject of a paper read on December 15 before the Institution of Civil Engineers by Mr. A. H. Naylor, who was chief assistant engineer to Mr. B. N. Peach, the resident engineer for the undertaking under Messrs. C. S. Meik and Halcrow of Westminster, the consulting engineers responsible for the design and supervision of the works from their inception. The following information of interest is extracted from Mr. Naylor's paper. Reference should be made to the map of the district which appeared in the issue of NATURE mentioned above.

The second stage comprises essentially the collection of the discharges from the Loch Laggan and Loch Ossian catchment areas into a reservoir formed by the construction of a dam at the western end of the former and the diversion of the impounded water through a tunnel to Loch Treig, with the provision of further storage through the construction of a dam at the northern end of Loch Treig. Loch Treig is the main storage reservoir of the system, and the construction of the dam raises the overflow level from the original height of +784 ft. O.D. to +819 ft. O.D., a capacity of 7,838 million cub. ft. being obtained above the lowest level (+695 ft. O.D.) to which it can be drawn down. By arranging that the Loch Laggan reservoir should be capable of being drawn down to +804 ft. O.D. and should spill at +820 ft. O.D., a further storage capacity of 1,480 million cub. ft. is rendered available. The tunnel connecting the two lochs, constructed almost entirely through rock of good quality, has a fall of 15 ft. in its length of 2¾ miles. The cross sectional outline is made up of circular segments, giving a width inside the concrete lining of 14¼ ft. and a height of 13½ ft. Three streams passing over the tunnel are diverted into shafts leading into the tunnel.

The Laggan dam is noteworthy as representing the first instance in Great Britain of the embodiment of a large siphon spillway in the design. Six siphon units are installed having shaft diameters of 4 ft. 6 in., fitted with jet dispersers at their outer extremities, the intakes being 3 ft. high by 6 ft. 10 in. wide. By inclining the outlets at 30° above the horizontal, it is calculated that the issuing jet will strike the river bed at about a maximum distance from the toe of the dam and reduce to a minimum the danger to the dam from vibration or undermining.

For the third and final stage of development it is contemplated to divert the waters of the upper Spey westward into the River Pattack which flows into Loch Laggan, so that, whereas originally the River Spean flowed into the River Spey to discharge into the North Sea, under the projected scheme, the Spey will flow into the Spean and discharge into the Atlantic Ocean.

BRYSSON CUNNINGHAM.

Forestry Research in the Malay Peninsula

THE annual report for 1935 of the Forest Research Institute of the Malay Forest Department has been recently issued, as also the Programme of Research for 1936 (Kuala Lumpur: Forest Department, 1936). Owing to financial difficulties, these reports are reproduced from typescript.

The Institute has been under Mr. J. G. Watson and Mr. E. J. Strugnell during the year. The cost of maintenance is a charge on the budget of the Forest Department, and this in recent years of financial depression has necessitated considerable economies. It is said that the funds available for apparatus and travelling have been limited, and it has been impossible to provide technical subordinates, to whom a great deal of the routine which has fallen on the shoulders of the senior staff could have been entrusted.

The curtailment of research work has been taking place in many parts of the British Empire; but it is a short-sighted policy where existing unworked and only partially known tropical and subtropical forests are concerned, which represent a part of the capital assets of the country containing them. It is this want of recognition that the large forest tracts in so many of the Dependencies and Colonies of the British Empire represent an undeveloped capital of considerable potential value upon which funds must be put out if it is to be developed (as in the case of the primary development of a gold or other mines) which is delaying progress; whilst in many cases the forest capital is deteriorating in value under the current and injurious practices of the users.

The report deals with the work of the various branches of the Institute—sylviculture, botany, wood technology, timber mechanics, seasoning and wood working, timber preservation and durability, and the investigations carried out in the chemical and entomological branches. A brief description of the education work carried out at the Forest School is appended to the report.

The work described for the year indicates the wide field which is now being covered by the research officers, and a careful study of the report proves that research work of the very highest value, not only to the Department concerned but also to the country as a whole, is being carried out.

The programme of research for 1936 indicates the lines of work to be undertaken under the different branches; but in some cases it is noted that suggested work must be postponed until there is an officer available to undertake it.

In the *Malayan Forest Records*, No 12 (Malay States Govt. Caxton Press, Ltd., Kuala Lumpur, 1936), Mr. H. E. Desch, wood technologist, discusses "Commercial Timbers of the Malay Peninsula. No. 1, The Genus *Shorea*", botanical notes being contributed by the forest botanist, Mr. C. F. Symington. Mr. Desch had started a series of articles on Malayan timbers in the *Malayan Forester* but gave them up in order to concentrate on the production of this record, as a new method of treatment had become necessary.

"Further investigation disclosed," says the author, "that the then-accepted groups, in the case of timbers of the genus *Shorea* particularly, were arbitrary and unworkable. For example, having described the timber of *nemesu* (S. pauciflora), it was found that the description fitted timbers of the *meranti tembaga* (S. leprosula) type in most essential respects, while the timbers of species allotted, at that time, to the *meranti bakau* group were not really dissimilar. It was apparent that the attempt to set up divisions in a group of timbers so similar to one another was impracticable, while the assumption that differences did exist was responsible for some of the prevailing misconceptions and might well lead to further inaccuracies." Mr. Desch therefore decided to classify the timbers of a genus on their anatomical structure, general appearance and physical properties, irrespective of existing conceptions of classification. The first genus to be so treated was *Shorea*, the most important source of timber in the Peninsula, and it has been found that the classification of species conformed closely with Mr. C. F. Symington's parallel botanical studies.

Concentrating on the more salient features of groups of species, 47 species have been dealt with in six more or less natural divisions, but repetition has not been entirely eliminated. This overlapping was felt to be unavoidable until features of specific significance are better understood.

The treatment of his subject is both useful and instructive and although, as Mr. Desch says, the publication is a compromise in an endeavour to cater for those interested in the scientific study of wood. and those engaged in the practical utilization of timber, it is none the less interesting for that reason.

Education in England and Wales*

THE report of the Board of Education for the year 1935, published under the title "Education in 1935", is, in the main, like those of previous years. The volume is, as usual, a compendium of facts and figures duly arranged in successive chapters, dealing all too briefly with subjects which range from the elementary school to adult education, as well as the museums at South Kensington and Bethnal Green which are financed out of the Board's vote, and the whole miscellany is supplemented by tables of statistics, of which it may safely be said that they are more detailed and elaborate than those which are supplied by the Ministry of Education of any other European country. It is, in fact, not so much an account of 'Education in 1935' as a bare record, with little by way of comment or suggestion to relieve it, of the Board's administration during the year in question.

In one respect, the report makes a welcome new departure. The year of King George V jubilee has provided an occasion in an opening chapter for an interesting survey of education since the King's accession in 1910, a period which has witnessed "a more conscious recognition of the claims of the individual and a greater emphasis on the development of each child according to his bent and capacity". Though there is no room for complacency, it will scarcely be denied that there has been marked progress over the whole field. The abolition of half-time attendance at elementary schools, and of exemptions before fourteen years of age, has resulted in an increase of 87 per cent in the number of children over thirteen in these schools; out of 20,854 schools, 4,760 are new or have been extensively enlarged; the education given in the schools is less bookish and more practical, the percentage of schools for children over 11 which make provision for handicraft having risen from 23 in 1910 to 65 to-day: lastly, the re-organization of the elementary system with its provision for "advanced instruction", as adumbrated in the Hadow Report, though long overdue and still incomplete, has at least gone so far that 55 per cent of the older children are in reorganized schools.

The developments in technical education include the establishment of grouped courses and of the scheme of examinations for National Certificates. The provision in the Act of 1918 for a system of part-time day continuation classes for adolescents of 14–18 years is discreetly referred to as "a plan which would . . . have had a profound influence on the system of Technical Education and the relations of the schools with industry and commerce". This is an understatement. It would, we think, be true to say that this provision of the 1918 Act, had it been implemented, would have had social and educational results not less important than those which have followed from the Act of 1902; and the failure of successive Governments to tackle the problem of adolescent education is one of the most lamentable omissions of post-War statesmanship.

As for secondary education, the years from 1910 to 1935 cover nearly the whole period during which secondary schools have existed as an integral part of the State system of education. The growth in the number, size and efficiency of these schools, in which the elementary school teacher of to-day will usually have been educated and from which the technical schools and colleges now derive a large proportion of their students, may justly be regarded as the most notable educational advance of King George V's reign. The extent of that advance can only be measured by comparison with conditions in pre-War days, when teachers were ill-paid and too often ill-qualified for their important tasks, when the pupils came late and left early—the average length of school-life being less than three years—when nothing had been done to co-ordinate examinations or to reduce their number, when sixth form work was ill-developed and the flow of secondary school pupils to the universities was in some areas a mere trickle and in a large number of schools non-existent. For information as to the conditions which exist to-day the report must be consulted.

---

* Education in 1935, being the Report of the Board of Education and the Statistics of Public Education for England and Wales. (London: His Majesty's Stationery Office, 1936.) 3*s*. 6*d*. net.

In regard to the output to the universities, Table 48 shows that 36 per cent of all the entrants in 1934–35 entered direct from State-aided secondary schools, and this figure does not take account of those who entered after an interval. The figures given on page 49 of the report show that 53 per cent of the open scholarships and exhibitions awarded at Oxford and Cambridge were won by pupils from the State-aided schools, and that in 1935 candidates from these schools gained 56 per cent of the first classes in the final honours schools and triposes (Part II) awarded to candidates from all schools in England and Wales. The flow of pupils to the universities has been encouraged by the institution of State scholarships, which will in future be open to candidates from 'public schools' as well. As to the after careers of the State scholars, it would appear that, in the period 1929–34, 50 per cent of these scholars (men 34 per cent, women 70 per cent) took up teaching, 20 per cent entered other professions and 13 per cent engaged in research. These figures, compared with corresponding figures for the previous five years, show a decrease of 8 per cent in those who entered teaching, an increase of 6 per cent in those entering other professions and 5 per cent in those who took up research work.

It may well be asked whether the report has anything to tell us as to what is actually going on in the class-rooms, practical rooms and science laboratories of the schools with which it deals. The answer must be in the negative. The scientific reader who wants, for example, to know what steps are being taken to devise a general syllabus of elementary science and whether biology is now receiving the attention it deserves, will find no answer to his question in the volume under review. Containing as it does much information which those engaged in educational administration will be glad to have at hand and, in its initial chapter, a valuable survey which the general reader may study with profit, it tells us scarcely anything of the actual work of the schools. Statutory requirements no doubt determine the form of the Board's report, and may to some extent limit its contents; but it is permissible to suggest that if the omission to which we have directed attention could in a measure be made good, the Board's annual reports would be of more general interest and incidentally secure a wider publicity.

F. B. STEAD.

Immunity of Plants to Disease

THE third International Congress on Comparative Pathology met at Athens on April 15–18, 1936, and there were three main sections, namely, human medicine, veterinary medicine, and plant pathology. Reports of the various deliberations are now being published, and the first volume, from the Section of Plant Pathology, deals with plant immunity against disease-producing agents*.

Dr. E. J. Butler reviewed the problem, and after insisting upon the relatively local reactions of plant tissue, through absence of any circulatory system, he recognized five types of immunity, namely, (1) that following a previous infection and affecting the whole plant, (2) resistance to further local infection in the immediate region of a previous attack, (3) immunity by 'vaccination' with a less virulent strain of the pathogen or of substances formed in diseased tissues, (4) intracellular acquired immunity, and (5) symbiosis, which might vary towards immunity with changing conditions.

Dr. J. Dufrenoy considered the role of amino acids and phenolic compounds in susceptibility or resistance of plants. He showed that resistance is due, not so much to the pre-existence of phenolic compounds in healthy plants before attack, as to the ability of the host to produce such substances when under the stimulus of the entering fungus. Several plant diseases exhibit zones of cells rich in anthocyanin or phenolic compounds. around the point of fungal attack. In *Vitis* hybrids, many concentric zones follow attack by mildew, each made during a dry period. The intervening green zones indicate moist intervals.

Several interesting comparisons between animal and plant pathology were drawn by Prof. Ernst Gäumann. Animal immunity is more active than plant immunity, since animal parasites are introduced passively into an active host, whilst plant parasites must themselves gain entrance to a relatively passive victim. Prof. Domenico Carbone agreed with many speakers at the Congress, that there is no evidence for the formation of definite antibodies in plants; but described the diffusion of defensive substances from pieces of plant tissue kept in solutions, or gels, *in vitro*. Dr. J. Magrou maintained that phenomena which might be termed phagocytosis appear in the plant kingdom. Mycelial masses of the symbiotic mycorrhiza of orchids are, for example, often digested by the host.
